No. 11172. A neurotic young woman with intestinal indigestion, presented acute dermatitis venenata on the arm of four days' standing. She was given the dilute poison oak solution in ascending doses, increasing up to one teaspoonful three times daily. A soothing alkaline lotion also was given. The trouble cleared up in a week but ten days later, following exposure, she had a slight recurrence on the wrists.

No. 11249. A middle-aged man had generalized acute dermatitis venenata of two days' duration. Exposure to poison oak had occurred the day preceding the onset of the eruption. He was given an injection of 1 cc. of the toxin and the dilute solution by mouth, and the next day showed some improvement, but new areas appeared on his arms and legs. A soothing alkaline lotion was ordered. He was given a second injection and never returned, so it is not known whether or not recovery occurred shortly afterwards. We believe that he would have returned if not very much better.

No. 11593. A young woman was exposed to poison oak and the following day presented an acute dermatitis on the arms and face. She was not given an injection, but the dilute solution was prescribed in the usual way and also a soothing alkaline lotion. The next day the dermatitis venenata increased very much in severity, but on the following day much improvement was noted. The patient did not return.

Of the doubtful, or incomplete cases, there were twelve (12%). These included only those patients who were given the toxin treatment and never returned. Certainly most of them would have reported had the condition grown any worse or had not subsided promptly.

Thus, it will be seen, that this low estimate of 80% of successes is a conservative one.

The poison oak toxin is prepared in two strengths, "concentrated" and dilute. It is now made and sold by two recognized local and one eastern pharmaceutical house. These preparations consist of alcoholic solutions of the toxicodendrol which have been tested and standardized.

The present method of specific treatment is as follows:

If the lesions have begun to subside no injection is given, but the dilute ("immunizing solution") is administered internally, starting with ten drops, giving it three times daily, increasing by one drop each dose until twenty drops are reached. Then one teaspoonful is ordered once daily and gradually the dose is increased to two teaspoonfuls daily. In every case an effort to develop immunity is made by having the toxins taken steadily for two or three weeks.

In acute cases an intragluteal injection of 1 cc. of the concentrated poison oak toxin is given at once. This is repeated in twenty-four hours if improvement is not shown. Then the dilute solution is given by mouth as already outlined. Ordinarily one injection is sufficient. Sometimes two, and occasionally, three, are needed. If injections are contraindicated for any reason, one ampoule (1 cc.) of the concentrated poison oak solution is given by mouth and repeated in twelve hours and the dilute solution then given in ascending doses.

For immunization, the dilute solution is prescribed in ascending doses, starting in with ten drops. Patients are advised to start taking the preparation several weeks before going to the country and to continue a week or so after arriving there. As the object of this treatment is to develop increasing tolerance for the poison *steady uninterrupted medication* is essential. A high degree of tolerance and almost complete immunity may be produced.

My own extensive experience with the method and numerous observations reported in letters and otherwise by others proves, in my opinion, that this treatment of poison oak dermatitis is efficacious. Even were it effective in only 50 per cent of the cases it would be worthy of our endorsement and use, but we feel safe in stating that it succeeds in over 80 per cent of our cases, while some of our confreres claim over 90 per cent of good results.

The following references will be useful to those desiring to review the subject further:

DISCUSSION

WILLIAM GOODRICKE DONALD, M. D. (Berkeley)—It is with great pleasure that I welcome the opportunity to discuss Doctor Alderson's paper, if only to attest to the value of the use of the extract of the poison oak plant.

This has been in use at the University of California Infirmary at Berkeley since it was first put on the market and the staff are unanimous in the opinion that it has materially shortened the course of the disease.

During the last twenty-two months there have been 638 cases of poison oak dermatitis treated at the university infirmary, seventy-two of which were hospitalized for an average of three and one-half days. The average days treatment of the 638 cases was 3.1; 312 of these were treated once.

Those treated by poison oak extract were the more severe types and were treated on an average of 2.9 days. The cases considered not severe enough for expensive treatment were 151; these being treated by calamine lotion with 1% phenol as a rule. The average duration of treatment here was four days.

Poison oak extract was administered by hypodermic alone 188 times on 141 individuals. It was administered orally alone ten times on ten individuals. Seventy-five hypodermics, combined with sixty-eight oral mixtures, were administered to sixty-eight individuals, a total of 395 separate administrations on 267 individuals. Each individual on an average received 1.4 administrations of either hypodermic or oral mixture (90 c.c.) The period of treatment, I believe, is remarkably short in view of the fact that only the severe cases were given the poison oak extract.

Doctor Alderson mentions the local treatment used at the University of California Infirmary, where for the last year we have used liquid air to freeze the skin area affected by poison oak. In 1899, Doctor A. Campbell White (Medical Record) mentions the fact that liquid air, when applied to skin affected by poison ivy, was remarkable for the advance in its healing within twenty-four hours. This is the only mention I have seen of the use of liquid air for this purpose.

In October, 1923, Mr. Nelson, Mechanician of the Department of Chemistry, University of California, had severe poison oak dermatitis on his forearms. He had been making liquid air for some fifteen years and states that the obvious suggestion of getting together the hot arms

and the cold air was irresistible. He soaked some cotton waste with the liquid air and patted it on his arm. To his surprise and delight the skin where he applied the liquid air immediately ceased to itch and his arms healed rapidly. He tried this on students and others who had the dermatitis with similar results. Word leaked out around the east bay cities and people flocked to him for treatment. The newspapers took up the story and finally it came to the observation of the university infirmary.

After trying it on a number of cases we were convinced of the fact that in selected cases, if applied correctly, the itching would immediately cease and the area treated start to heal. We have used liquid air 516 times on 216 patients. We have used it in combination with poison oak extract 66 times on 48 cases. And we have used it alone 450 times on 230 patients, an average of two times a case. It is significant that the days treatment, during the year we have used it, has been 3.4 days, while during the corresponding period the proceeding year, without liquid air, these treatments were 3.7 days. But more significant is the fact that in 1924-1925, we have had to use poison oak extract on 24% of all cases, whereas in the year previous, we had to use it on 42% of all cases.

Liquid air can be had in the larger cities from any oxygen gas company at a very small cost. The objection is the length of time consumed by the application and its volatility. A liter lasts (without disturbing it) for about forty-eight hours.

We keep liquid air in a small necked open Dewar flask. We apply it usually by wrapping a few thicknesses of gauze around a 3/16 inch diameter cylindrical stick, soaking this in the liquid air and rolling it over the dry surface of the skin, with such speed as to leave about one-half inch frosted skin behind. Too prolonged application will blister badly; too short application gives only temporary relief. The optimum application causes immediate and lasting relief from the itching and healing starts immediately. Large soggy, edematous weepy areas are not so successfully treated in this way and can be better treated by applying a blast of dried air blown through the liquid air to freeze the skin.

We have evolved a routine treatment for the severe cases as follows:

- (a) Liquid air locally for the itching.
- (b) A hypodermic of poison oak extract, intragluteally, and two drams poison oak extract orally immediately and one dram t.i.d until 90 cc.s. have been used. We have very rarely found it necessary to give more than one injection.
- (c) Elixir of sodium bromide, one dram, four times a day. The value of bromide is great and personally I use it on all my cases.
- (d) Calamine lotion with 1 per cent phenol and 1 or 1½ per cent menthol and 15 per cent alcohol for the patient to take with him for local application on new spots not reached by the liquid air.
- (e) Boric ointment to be used when the skin is drying and desquamating.
- (f) Iced mg. sulph. comp. for odema.

Finally let me reiterate my firm conviction from the observation of many more than the above-quoted cases, that poison oak extract as described by Alderson is the best remedy we have at hand to halt the spread of the disease and that the local treatment of vesicles by freezing with liquid air gives immediate and lasting relief when applied correctly.

Casual Mechanism of Diabetes Mellitus—The casual mechanism of diabetes is conceived by A. E. Epstein, New York (Journal A. M. A.), to be as follows: Changes in the permeability of the capillary vessels can result in the passage of trypsin into the blood stream, and its ultimate entry into the liver via the portal circulation. The first effect of the mobilization of trypsin is a glycogenolysis with a consequent hyperglycemia and glycosuria; the second is the neutralization of insulin secreted into the blood stream, thereby causing a deficiency of active insulin. Epstein claims for his theory that it is in closer accord with experimental evidence and clinical phenomena of diabetes mellitus than any heretofore proposed.

OSTEOMYELITIS OF THE SKULL

By HOWARD FLEMING, M. D., San Francisco

A great majority of the cases reported have followed frontal sinus and mastoid infections.

Cases may be classified into two types: So-called primary, spontaneous or hematogenous osteomyelitis, and the secondary or contiguous variety.

Cases of skull involvement following osteomyelitis of the long bones are comparatively rare.

The treatment of osteomyelitis presents a serious problem.

Attempts at plastic repair of bone and scalp defects should be delayed until all evidence of infection has subsided for some time.

Recommended methods of treatment differ widely, and the surgeon cares for the isolated case with little authoritative help.

Discussion by Carl W. Rand, Los Angeles; Edward A. Franklin, Los Angeles; Howard C. Naffziger, San Francisco.

A PERSONAL interest in this subject was stimulated by the care of a patient who has resisted all forms of treatment during the last twelve months. The literature and textbooks lead one to believe that osteomyelitis of the skull is a rare occurrence. Scheinziess, out of a series of 1782 cases of osteomyelitis of the long and flat bones, reports only ten cases involving the skull. The number of cases seen recently suggests that this complication is far more common than supposed. Judging from the literature, osteomyelitis of the skull has been of most interest to the ear, nose, and throat specialist. A great majority of the cases reported have followed frontal sinus and mastoid infections. Osteomyelitis, as a complication of trauma of the skull, has received little attention, and this paper is largely devoted to a consideration of this type.

Pott first described the disease in 1778. He advanced the idea that symptoms were due to a bone contusion and extradural hemorrhage. There was an interval of just one hundred years until Van Launelongue described what we accept as the real etiology and pathology.

Cases may be classified into two types, i. e., the so-called primary, spontaneous or hematogenous osteomyelitis, and the secondary or contiguous variety. Our views regarding the etiology and pathology of infections of the skull are essentially the same as those advanced for osteomyelitis of the long bones. Trauma and local injury produce a period of lowered resistance, preparing an ideal field for bacterial invasion.

Previous infections play an important part, and the staphylococcus is the principal offender. A careful history will in a great majority of cases reveal previous infections that may be considered predisposing or exciting factors. Furunculosis, perinephritic abscess and infected wounds often leave residual foci ready to invade devitalized tissues. In a small number of cases the other cocci, as well as typhoid and influenza, have been reported as the infective organism.

Cases of skull involvement following osteomyelitis of the long bones are comparatively rare. Those cases reported in which this has occurred usually had multiple long bone infections prior to that of the skull. Metastatic infections of other bones following osteomyelitis of the skull is still less frequent.

The frontal bone is most often the seat of infection. The order of incidence of infection in the other bones is temporal, parietal and occipital. The contiguous sinuses and middle ear will explain the order of frequency. Fortunately the spread of infection is most often toward the vertex rather than the base. In children the periosteal partitions may localize the infection to one bone. These barriers are not marked in adults, and the disease may spread rapidly from one bone to another.

Those cases following sinus infection the otolaryngologists have classified as spontaneous and post-operative. In both an infected sinus is the primary cause. Osteomyelitis following operations on a sinus is said to have a mortality of 100 per cent, while that appearing without operative trauma has a mortality of only 60 per cent. No satisfactory explanation of this discrepancy is available, although most authorities are agreed as to the figures.

The pathology is essentially the same in all types. Inflammatory changes appear in the scalp. There is oedema and swelling, but frequently no redness. More often the doughy tumor mass is pale and anemic, suggesting a cold abscess. These tumor masses may be multiple and usually overlies necrotic bone. The origin of the infection is in the diploe. The diploic structures melt away and are replaced by granulation tissue. Frequently, the blood vessels are infected and thrombosed far beyond the visible extent of pathology. The inner and outer tables become anemic and lose their characteristic appearance. The normal color is replaced by a glistening pallor and the eburnated bone breaks up into large and small sequestrae. Fortunately, the pericranium is less resistant than the dura and subgaleal abscesses appear. The dura usually shows a typical pachymeningitis externa. The microscopic picture is that of a purulent rarefying osteitis.

Symptoms are usually not severe until the onset of complications. One is frequently amazed at operation to see the severity and extent of the pathology in patients with most insignificant symptoms. In a small percentage of cases the course is acute, with the characteristic picture of osteomyelitis elsewhere. More often, and especially in those cases following trauma, the symptoms are mild and the course exceedingly long. Many cases persist from one to two years, and are operated on ten to twenty times.

Osteomyelitis of the skull in babies following birth trauma, is illustrated by three cases in this small series. All were essentially the same, and a description of one will be sufficient.

The patient was the first child of young parents. The pregnancy was normal, but the labor difficult. Following delivery by forceps, large oedematous swellings were noted over both parietal regions and the left side of the neck. It was noted that the left side of the face did not move as well as the right, the eye remaining open, and the mouth drooping. The left eye slit and pupil was smaller than the right. No weakness of left hand and leg was noted. The swelling in the right parietal region did not subside, and at the age of one month became reddened and inflamed. On two occasions yellow greenish pus was evacuated.

The baby was nine weeks old at the time of the examination. The swelling had subsided somewhat. There was a left facial paralysis of the peripheral type; also a left endophthalmus and inequality of pupils, the right being larger than the left. All nerve findings were thought to be due to the peripheral seventh and sympathetic nerves. No evidence of central irritation or damage was found. X-rays revealed a decalcified area the size of a dime in the right parietal bone.

Operation uncovered a small area of osteomyelitis and pachymeningitis externa. Cultures taken of the purulent matter were reported positive for staphylococcus aureus. The wound continued to drain for some time, but eventually healed.

It is very possible that many of the so-called infected hematomas seen in new-born babies are in reality cases of low-grade osteomyelitis. Frequently, the virulence of the infecting organism is low and the resistance high, and no doubt spontaneous healing occasionally takes place.

The second case is characteristic of a series of three. A man 45 years old was injured by having his head crushed in a cement block press. The vault was so badly dislocated from the base that the emergency surgeon did nothing more than reshape the head and put the skull cap in place. The patient bled profusely from the nose and both ears for sixteen hours. To everyone's surprise he made an uneventful recovery. Six months after the accident the following findings were noted. Marked asymmetry of the vault; anosmia; right-sided primary optic atrophy, and hypesthesia of the left side of the face. During his convalescence the patient had erysipelas and acute suppurative arthritis of the ankle, which necessitated drainage. Two months after this complication an abscess and sinus appeared over the skull fracture line, which had been well fibrosed. Operation revealed an osteomyelitis and pachymeningitis. The fistula was permanently closed in about six weeks.

This case offers many points of interest. The question arises whether a latent infection in the skull injury was responsible for the arthritis, or the arthritis of the ankle was the etiological factor causing the osteomyelitis of the skull. It is also possible that there was no relation between the two or that both were due in turn to some third focus of infection. The facts would rather suggest that the skull injury produced an area of lowered resistance susceptible to the invading organism present during the acute suppurative arthritis.

The third case is the one that prompted a review of the literature and report of these cases. Injured over one year ago, the patient is still unhealed. A man of 43 was struck in the right parieto-frontal region by the handle of a derrick wheel. He suffered a long scalp wound and a comminuted fracture of the skull. The wound was sutured to control bleeding. About ten days after injury the wound began to discharge pus. At the time of our first examination he had a widely separated scalp wound. The bone fragments appeared pale and glistening. Synchronous with each pulsation a yellow purulent material exuded from the fissures.

X-rays revealed marked fragmentation of right parietal region and fracture lines extending to the base.

At operation the fragments of bone were found to be large sequestra of the outer table only. These were floating in pus. All loose fragments were removed and the margins of the periphery rongeured away. All diseased-appearing bone was removed and healthy dura exposed on all sides. The wound was sutured in part, leaving ample drainage.

Since the original operation, seven attempts have been made, either to remove the infected bone or close the defect in the scalp. Nearly all the measures recommended as effective in the treatment of osteomyelitis have been tried, without permanent success. So much skull and scalp have been removed and lost by repeated operations that the defect is alarming. Bone has been removed from the midline on the vertex to the zygomatic arch, and the longitudinal dimension of the defect is larger. Recent x-rays suggest an extension of the osteomyelitis to the left side.

The last two operations were attempted with the conviction that only the most radical measures would effect a cure. All suspicious-appearing bone was rongeured away and the rough edges smoothed down with a chisel. The use of the chisel was the result of a suggestion by Doctor Edward Bull. It was thought that devitalized bone on the margin of the defect was produced by the crushing effect of the rongeurs, and increased the danger of spreading the infection. With a sharp gouge or chisel, the rough edges may be eliminated without traumatizing the residual bone. In dissecting the galea every precaution was taken to avoid injury to the pericranium. However, in spite of these precautions, signs of further infection appeared, necessitating opening the wound widely.

Prior to the injury and bone infection, the patient states he was singularly free from all skin infections. During the last year he has had numerous boils and furuncles. It would seem that the patient had lost all resistance to the staphylococcus organism.

The last case is one of osteomyelitis following operation on the frontal sinuses. A middle-aged man had radical external operations on both frontal sinuses. Progressive symptoms suggested intracranial complications. The frontal bone was found to be involved in an infectious process extending from the sinuses. A large cerebral abscess was evacuated from the frontal lobe. The fatal outcome adds another case to substantiate the 100 per cent mortality figures for such cases.

The diagnosis and treatment of bone injury and infection is of primary interest only to the surgeon. The complications of osteomyelitis of the skull often present interesting and difficult neurological problems. These complications, in the order of frequency, are extradural abscess, pachymeningitis, leptomeningitis, cerebral abscess—subdural abscess and sinus thrombosis. The infection travels by direct extension through contiguous surfaces or along the route of the cranial nerve sheaths. In some cases the large sinuses are infected by way of diploic and emissary veins.

If the cerebral pathology occurs in the so-called silent areas, repeated neurological examinations may fail to localize the site. Often an abscess may obtain considerable size and produce signs of marked intracranial pressure without producing signs of localizing value. In cases where cerebral abscess occurs as a late complication of osteomyelitis, the abscess is usually in the immediate vicinity or underlying the diseased bone. In the more virulent cases the abscess may be found at some distance. No doubt those cases are due to metastatic or embolic causes rather than direct extension.

The treatment of osteomyelitis presents a serious problem. The proper care of head injuries, especially compound fractures, will prevent a large number of cases. Every case should be considered potentially if not actually infected. Cases seen in the first twenty-four hours may be debrided and closed. Those seen at a later time should be left wide open.

Any scalp wound that fails to heal promptly should lead one to suspect an underlying osteomyelitis. Frequently, x-rays do not reveal evidence of osteomyelitis until the process is well advanced.

Local anesthesia is well adapted for use in these cases if the infiltration can be made at some distance from the infected area. The bleeding is minimized, making exposure and inspection easy. Wound edges and sinuses should be excised. All loose fragments should be removed and, in addition, a margin of what appears to be healthy bone. The appearance of the dura is often the best indication of the extent of the pathology. Care must be taken to avoid trauma to the dura. In those cases where intradural complications are suspected, a careful inspection and palpation of the dura will often reveal evidence of a stalk or sinus leading to the underlying pathology. In such cases the abscess cavity may be drained without gross infection of the surrounding tissues.

Frequently, the surgeon is loathe to excise as much bone as experience with such conditions would dictate. Unless one makes it the rule to remove a wide margin of supposedly healthy bone, repeated operations and poor results will occur. Care must be taken not to disturb the pericranium beyond the line of excision. The rough margins following the use of rongeurs can be smoothed off with a chisel with slight trauma.

Attempts at plastic repair of bone and scalp defects should be delayed until all evidence of infection has subsided for some time. Frequently, infection remains dormant when the tissues are fully exposed, only to flare up when closure is attempted. Too hasty or ill-advised attempts at closure sacrifice covering tissues, and adhesions between galea and pericranium interfere with later efforts.

Several other methods of therapy may be used as adjuncts to surgery. Local disinfectants, such as mercurochrome, gentian violet, alcohol, and iodine have proved useful. Autogenous vaccines and intravenous dye therapy have given good results as accessory agents. German authorities highly recommend the use of various artificial lights.

In conclusion, let me urge that more cases of osteomyelitis of the skull be reported. It would ap-

pear that the prevalence and seriousness of this complication has not been properly emphasized. Recommended methods of treatment differ widely, and the surgeon cares for the isolated case with little authoritative help.

380 Post Street.

DISCUSSION

DR. CARL W. RAND (Pacific Mutual Building, Los Angeles)—I did not know that osteomyelitis of the skull was so rare. The few cases which I have seen have been secondary to frontal sinusitis or mastoiditis, or resulting from compound, comminuted skull fracture. One instance was that of a new-born child with infection following instrumental delivery which spread under the pericranium. This yielded to sunlight treatment. When he was seen five years later, a definite thickening of the skull in this region was felt. I would emphasize greater care in the early treatment of cases of compound skull fracture. If the tissues are very carefully handled and thoroughly cleansed, not infrequently the loose fragments of bone can be saved without resulting osteomyelitis. Once this pathology exists, however, general upbuilding of the patient is an important adjunct to surgical interference.

EDWARD A. FRANKLIN, M.D. (Bank of Italy Building, Los Angeles)—Closer co-operation between internist and surgeon is clearly indicated in osteomyelitis. One of Doctor Fleming's cases in which healing has resisted frequent and extensive surgical procedures owing to lowered resistance of infection, emphasizes this fact.

Haemic and metabolic studies are of prime importance in discovering associated complications engendered by enforced and unhealthful change of patient's environment during prolonged hospitalization. Special hygienic and dietetic measures suited to the individual are of prime importance as an adjuvant to surgical treatment.

HOWARD C. NAFFZIGER, M.D. (380 Post Street, San Francisco)—In the treatment of osteomyelitis of the skull one is often impressed by the tendency of the infection to spread for long distances along the diploic channels. These must be followed to their terminations. With soft dural granulations and purulent collections between dura and bone, extensive removal of the full thickness of bone seems imperative. When, however, there is only bare, porous appearing outer table, with perhaps some diploic infection, free removal of the outer table or multiple perforations of the outer table alone as suggested some years ago by Dr. Charles Mayo serves to permit vascularization of the area and permit rapid granulations with separation of the outer table. Such a plan leaves a bony covering over the dura and epithelization is rapid. In such cases large bone defects can be avoided.

In one instance I have seen a subgaleal abscess occur in the course of a septicaemia. When this patient was first examined he presented also a hemiplegia of the opposite side of the body and his optic discs were choked. Incision of the scalp abscess revealed denuded, porous-appearing bone. An opening through this bone revealed no pus in the diploe, but the dura was soft, thickened and blotter-like. Puncture of this revealed a huge intra-cerebral abscess. In a second patient a scalp abscess was similarly associated with an intra-cerebral abscess with but little gross change in the intervening bone. Scalp abscesses associated with signs of intra-cranial involvement should cause us to keep such collar-button collections in mind.

Another experience with a staphylococcus infection complicating a luetic osteomyelitis makes me feel that this combination likewise should not be forgotten. In these, sufficient perforations in the bone to give adequate drainage for the acute infection should be followed by intensive anti-syphilitic treatment before any more radical operative treatment is instituted.

DOCTOR FLEMING (closing)—I heartily agree with Doctor Rand and Doctor Franklin that all medical measures that will be helpful and increase the patient's general resistance must be used in conjunction with surgery. However, osteomyelitis of the skull requires the same surgical drainage and prompt measures given bone infections elsewhere.

It may be of interest to note that the third case reported in the paper is now entirely healed. A plastic operation done a short time after the writing of the paper covered the defect with scalp and galea except for a small area. Scar tissue eventually covered the exposed dura. There is no sign of inflammation and we are hopeful that the lesion is permanently healed. The patient is back at work, but occasionally has attacks of weakness in the left arm and hand. At some future date another attempt to cover the dura entirely with normal scalp will be made.

THE ARTIFICIAL FEEDING OF NEWLY BORN INFANTS

By WILLIAM M. HAPP, M.D., Los Angeles

The birth-weight loss can be prevented by the supplementary feeding of a sufficiently concentrated food.

The procedure is not indicated in full-term babies of seven pounds or those nursing normal mothers.

The indications in which the prevention of the birth-weight loss is desirable are chiefly prematurity, small infants, post-partum illness of the mother, and twins. In these instances serious subsequent consequences in the infant may be avoided.

The digestive tract of the newly born infant can tolerate a fairly concentrated food, the advantages of which are outlined.

DISCUSSION by Harold K. Faber, San Francisco; Herbert M. Coulter, Pasadena; J. C. Cummings, Carpinteria; Victor E. Stork, Los Angeles.

NEWLY born infants, as is well known, lose weight after birth, and recover the loss after eight to ten days, sometimes longer. This phenomenon has been called the "physiological loss of weight in the newly born,"—physiological because it occurs in normal infants, nursing normal mothers. Physicians have attempted to explain the loss as a natural process, and have assumed that nature did not intend that the infant take food just after its birth and so supplied it for several days with colostrum, a fluid of relatively low nutritive value. Breast milk, in most cases, becomes ample only after the first week. Recently, the physiological nature of this initial loss has been questioned, and many workers now regard the loss as due to a state of semi-starvation, which is not only unnecessary, but in certain instances becomes of serious moment, especially in weak infants or in those prematurely born.

Figures from various sources show that the loss in weight during the first few days of life in normal breast-fed babies amounts to 8 to 10 per cent of the body weight. This loss is greater in first-born than in subsequent babies. (See Chart I.)

Coincident with the loss in weight there is an elevation in temperature, usually called dehydration or inanition fever, which is present in proportion to the loss in body weight. Practically all normal babies losing as much as 10 per cent of their body weight have elevations in temperature, if no means be taken for its prevention. (Chart I.)

CHART I

(From Von Reuss)

The upper figures give the average birth weight loss for various weights. The lower figures show the increasing loss in weight.

AVERAGE BIRTH WEIGHT LOSS PER CENT			
Weight		(Hery and Pies)	
Gms.	Lbs.	Primiparae Per cent	Multiparae Per cent
2000-2500	4.4- 5.5	9.3-11.2	7.6-8.2
2510-3000	5.5- 8.6	7.1- 8.3	6.3-6.2
3010-3500	6.6- 7.7	7.4- 9.0	5.6-8.1
3510-4000	7.7- 8.8	6.0- 9.7	6.1-8.7
4010-4500	8.8-10.0	6.6- 8.4	5.9-8.3
Average		9.3	8.0

AVERAGE FOR INANITION FEVER	
Birth weight Loss—Gms.	Fever Per cent
200	0
200-300	5.4
300-500	26.3
500-720	55.5

Let us consider briefly the factors behind these two phenomena. There is a theoretical loss in the first twenty-four hours after birth, due to the loss from the body of the following: meconium; vernix, caseosa; urine, drying. This amounts, in the average seven and one-half pound baby, to about 5 ounces. This loss only can be interpreted as physiological. Further loss represents the negative difference between the actual minimum requirement of the baby and the amount of the food ingested.

According to the studies of Heubner, Benedict and Talbot, and others, the basal requirement during the first ten days of life is 40 calories per kilogram, the maintenance 65, and the optimum about 100 calories per kilogram.

In addition to meeting its basal metabolism, which is 45 to 55 calories per kilogram, the newly born infant must receive, to remain in equilibrium and to gain in weight, additional food to account for growth, 10 to 20 calories per kilogram, digestion 4 to 6, muscular activity 20 to 30, and waste 8 to 12, making a total of 87 to 123 calories per kilogram required (Faber). (See Chart II.)

Taking the figures of von Reuss for the actual intake of breast-fed babies, determined by weighing before and after nursing, we find that the infant receives during the first twenty-four hours practically no food, during the second, about 30 calories per kilogram, etc. Not until the fourth day does he receive his maintenance requirement of 65, and at no time during the first ten days does he receive his optimum.

The result is that, during the first four days, there is a loss in weight beyond the purely physiological. The curves given by Faber (dotted line, Chart II) show even lower intake than those of von Reuss, and in his studies the basal requirement is not reached until the sixth day, and at no time during the first ten days was the maintenance requirement met.

In addition to deficient food, the baby receives during the first few days deficient fluid, i. e., water. It has been shown recently by Schick, Bakwin, Bachmann, and others that the giving of fluid supplementary

to the breast will reduce but not prevent the birth weight loss, but that it will prevent the initial fever. The fever is, therefore, interpreted as a dehydration fever, preventable both by giving of additional food and additional fluid.

Fishberg cites interesting incidents to show that, for a long time, it has been the practice among the laity to prevent this initial loss by giving of supplementary food.

He states that Soranus, a Roman physician of the second century, cited the giving of honey to newly born infants, and, according to Turner, the natives of the Fiji Islands gave chewed-up cocoanut or sugar-cane mixture, and in ancient India infants after birth received honey, butter, and various plants containing sugar. The practice of giving sugar solutions was common in Europe. Nicholas Culpepper, in his Directory for Midwives, 1693, advises the giving of honey to the newly born.

Studies have shown, furthermore, that not only can the digestive tract of the newly born tolerate food immediately after birth, but that a variety of foods, such as sugar solutions, half-milk plus sugar, whole milk plus sugar, human milk alone or with sugar, given to newly born infants supplementary to the breast, prevent the initial loss of weight and the fever, and cause no digestive disturbances in the babies (Schick).

Animals nurse immediately after birth from fairly full udders, and the initial weight loss is insignificant as compared with human beings (Kehrer, quoted by Backman). The modern human mother fails to supply her infant with food, but this is not due to the failure of the infant to digest it. The digestive tract seems to be mature at birth.

On the obstetrical service at the Los Angeles General Hospital, I attempted to prevent the birth weight loss in a series of infants. These were taken at random by the nurse, and were per routine put to breast eight hours after delivery and nursed every four hours, following which they were given a bottle containing: Skim milk, 20 ounces; dextri maltose No. 1, 2 ounces. In other words, 10 per cent carbohydrate added to skim milk.

The caloric value of this mixture is approximately 24 calories per ounce, with the following percentages: Fat, 0.5; protein, 3.5; carbohydrate, 14.5; salts, 0.75.

The infants were offered 2 ounces, and the amount taken recorded. The mixture was chosen as one containing a high caloric value per unit of volume, the calories being made up chiefly by carbohydrate, as it is well known that infants tolerate relatively high percentage of carbohydrate, provided the fat be kept low. Taking the figures of von Reuss for the average breast intake, I computed, from the series of fifty infants who received supplementary feeding, the caloric equivalent. The results are shown in Chart III.

The average amounts taken are charted in calories. The upper weight curve is the average weight curve of the fifty infants. It shows that the average birth weight was seven and one-half pounds, the

* In this paper the term "supplementary" is used as synonymous with "complementary"; that is, a feeding given after the breast-feeding.

CHART II
Shows the requirement for minimum maintenance and optimum in the newly born. The upper curve shows the daily energy quotient for the babies on supplementary feeding in our series. The middle represents the E. Q. for breast-fed babies from von Reuss' figures. The lower dotted curve shows the E. Q. for breast-fed babies in Faber's series.

average loss in the first twenty-four hours 5 ounces, and following this no further loss, but a steady gain, reaching the birth weight on the fifth day, and at discharge at the tenth day averaging one-half pound over birth weight.

The explanation of this is found in Chart II. The basal requirement is met at the end of twenty-four hours, the maintenance on the second day, and the optimum on the fourth day. From the fourth day these babies received their requirement as calculated by Faber (87 to 123 calories per kilogram).

In none of these fifty babies was there any eleva-

tion of temperature, although elevations were common in the control babies.

This series and those of the above-mentioned authors shows conclusively that the birth weight loss can be prevented without harm to the baby.

I wish to emphasize that I do not recommend this procedure as a routine. In normal babies, with birth weights over seven pounds nursing healthy mothers, it is unnecessary. In the following instances, however, the indications for supplementing the feeding of the newly born baby are fairly definite.

CHART III

The upper curves represent the daily weight curves in the babies of our series, receiving supplementary feeding, and of von Reuss' average for breast-fed babies and the figures for total caloric intake below. The total caloric intake is recorded in the lower curves.

1. All babies with birth weight under six pounds.

2. All premature infants.

3. Babies whose mothers are ill, as after prolonged, exhaustive labor, operative delivery, Cesarean section, puerperal infection, eclampsia and nephritis, post-partum operation.

4. Twins.
- It must be remembered that, granting the indica-

tions for supplementing the breast-feeding, it is highly advisable to supplement with a food sufficiently concentrated to give an adequate number of calories in the smallest bulk. Babies will take, during the first twenty-four hours, only one-half to 1 ounce supplementary, and from the second to fourth day 1 to 2 ounces.

The older methods of feeding very weak mixtures,

such as half or one-third milk diluted with water, fails to give an adequate caloric intake, even though 2 ounces be taken. There is no harm in giving whole milk with some or all of the fat removed and with the addition of 5 to 10 per cent carbohydrate. Lactic acid may be added to the formula, although this was not done in the above series. There is good reason for believing that whole milk undiluted will be better tolerated if lactic acid be added.

Breast milk can be used as supplementary feeding, if sufficient amounts be obtainable, but it is advisable to add 5 to 10 per cent carbohydrate to further increase its caloric value.

The above principles of concentrated feeding, so popularized in recent years by Piquet and by Finklestein, are of inestimable value, not only in the feeding of the newly born supplementary to the breast, but in the artificial feeding of newly born infants whose mothers die at birth, and of premature infants. I have fed newly born babies deprived of mother's milk 2 per cent undiluted lactic acid milk plus sugar from birth, with steady gain in weight and without digestive disturbance.

It is extremely desirable to prevent the birth-weight loss in premature babies. The technical difficulties in feeding such babies are very great, and the initial loss may be sufficient to cause the death of the infant. As the caloric requirement is high (140-200 calories per kilogram) and the amount which the premature will take at a feeding is small, the indications for concentrated feedings are obvious. I have used breast milk with the addition of 5 to 10 per cent dextri maltose, and when this was not available either a two-thirds whole milk mixture or whole lactic acid milk, to which 5 to 10 per cent dextri maltose or karo syrup was added. In this way the optimum requirement can be supplied very early, and good gains in weight obtained.

CONCLUSIONS

1. The birth-weight loss can be prevented by the supplementary feeding of a sufficiently concentrated food.
2. This can be accomplished without harm to the baby.
3. The procedure is not indicated in full-term babies of seven pounds or over nursing normal mothers.
4. The indications in which the prevention of the birth-weight loss is desirable are chiefly prematurity, small infants, post-partum illness of the mother, and twins. In these instances serious subsequent consequences in the infant may be avoided.
5. The digestive tract of the newly born infant can tolerate a fairly concentrated food, the advantages of which are outlined.

523 West Sixth Street.

DISCUSSION

HAROLD K. FABER, M. D. (Stanford University Medical School, San Francisco)—It is well to point out again, as Dr. Happ has done, the fact that Nature's provision for the nutrition of the first two or three days of life of the human species is defective, and may lead—in the case particularly of premature or weakly infants—to unfavorable or even calamitous consequences if artificial assistance is not given. There has been too much superstition

of the perfection of Nature's arrangements, with a rather widespread belief in the turpitude of interference with them when other foods than breast milk are given to the new-born. The young of nearly all mammals take other food than homologous breast milk very soon after birth.

It is, of course, not necessary to give supplemental feeding to well-nourished, large infants until there is definite indication for it. Happ has wisely limited his indications to those infants whose store of body fat and water is presumptively small at birth.

Of much interest is Happ's statement that new-born infants in his service suffered no digestive disturbance from undiluted (though skimmed) cow's milk. This is certainly a sign of vigorous digestive function, since the interference with enzymatic activity caused by the buffer substances in cow's milk is considerable. The use of acid to lessen the buffer effect is now generally regarded as desirable, when undiluted milk is employed. This appears to be Happ's present practice.

HERBERT M. COULTER, M. D. (1949 Huntington Drive, Pasadena, Calif.)—It was my privilege to have been in Europe about the same time as was Dr. Happ and to have observed the work of Finklestein, Shick, and Pirquet regarding the supplementary feeding of the new-born infant. Pirquet had the same idea in mind as Happ, when he devised the *decinem siqua* as a means of determining the amount of food that an infant should have. Using the sitting height instead of the weight or age as an index, he found that it required, in terms of Nem., three-tenths of the sitting height squared for metabolism alone with an addition of from one-tenth for growth, and a further addition of from one-tenth to three-tenths for exercise. This figures out about 45 calories per kilogram for metabolism, 60 calories for metabolism plus growth, and from 75 to 105 calories for metabolism growth and exercise, varying according to the degree of exercise indulged in by the infant.

I quite agree with Happ, when he says that the new-born infant tolerates a relatively high percentage of carbohydrate when the fat content is kept low in a concentrated formula. During my service at the Los Angeles General Hospital, following the report of Meyer of Chicago, I used sweetened condensed milk, with the result that, out of a series of fifty babies fed on a formula containing about 22 calories per ounce, six of them showed no loss of birth weight and began to gain after seventy-two hours. At present, under the service of Metzner, honey is being tried out as a substitute for sugar. Shick found, in Vienna, that breast milk, augmented by the addition of cane sugar to the extent of increasing its caloric content twice or even thrice its original value, was well tolerated by the new-born and did much to diminish the length of time before the infant regained its birth weight.

There can be no doubt that breast milk is the best food for a new-born infant, and, by robbing Peter to pay Paul, and with the help of an Abt electric breast pump, we are able at the Los Angeles General Hospital to furnish enough breast milk for those groups of babies who require supplementary artificial feeding as set down by Happ.

As for a carbohydrate to further concentrate the breast milk, it would seem, from the foregoing data, that there are many, such as corn syrup, cane sugar, honey, and sweetened, condensed milk, which are cheap and may be purchased at the grocery store, in place of the drug store.

J. C. CUMMINGS, M. D. (Coast Highway, Carpinteria, Calif.)—The supplemental feeding of new-born babies is a very important factor in their welfare. Dr. Happ has weighed the problem in a most delicate form, and I wish to compliment him on the earnest, interesting, and instructive paper.

Regarding loss of weight in the new-born, I think there are several angles from which we might survey the field: First. Shock from unnecessary handling and sudden change of room temperature. Second. Dehydration. Third. Insufficient food.

During a visit to the obstetrical department of the Columbia University last year, I was interested in observing their delivery routine and follow-up treatment of the new-born. As a preventive to shock from sudden exposure to room temperature, they were using an electric-heated tent about four feet square which was arranged snugly over the mother's hips during delivery, and the

baby was washed and dressed before it was removed from the tent, which had an average temperature of 100 degrees F.

Supplemental feeding was started four hours following delivery, and all unnecessary handling of baby was eliminated, and all charts revealed an increase of weight during the first week.

During the past two years I have been feeding new-born babies 60 calories per kilogram of skimmed milk and dextro-maltose, four hours following delivery, and feel very much encouraged by this routine.

I am satisfied that the supplemental feeding that has been outlined by Happ is the proper procedure in retaining and increasing the weight curve in new-born babies.

VICTOR E. STORK, M. D. (Medical Office Building, Los Angeles)—The data, logic, and conclusions presented by Dr. Happ in this paper seemed to me perfectly sane, and in general they are in line with our present practice in infant-feeding.

One point, I believe, should have special emphasis, and at the same time slight modification. The point to be emphasized is that it is neither necessary nor desirable to prevent the initial loss in normal, full-term, well-nourished babies, by giving supplementary food. I know of no evidence to show that this type of baby suffers any ill after-effects from this initial loss in weight.

When one gives any sort of supplementary food to a new-born infant, the breast milk supply of that infant is put in jeopardy. It will be more difficult in that case to establish and maintain an adequate breast milk supply. The weaning process has been started. This is the real reason for avoiding supplementary feeding when it is possible to do so. This effect of extra food in diminishing the breast milk supply constitutes the danger which Happ has himself pointed out in another article on "The Feeding of New Born Infants," in the November number of *Better Health*.

When it is realized that the smaller, more feeble, or premature infants, constitute the very group which should, above all, receive an adequate amount of breast milk, it becomes obvious that considerable discrimination is necessary in choosing the infants who appear to need supplementary feeding.

Dr. Happ does not say whether he is usually able to discontinue the supplementary feedings after one or two weeks and establish an adequate breast milk supply. There is usually considerable difficulty in getting away from the bottle once it is started. So many small babies, twins, and even prematures, accept their initial loss in weight and do well later on exclusive breast-feeding, that I should be inclined to make the indications for giving extra food a little more limited.

When it does seem necessary, however, to prevent trouble by giving extra food, the method of doing this, outlined by Happ, seems entirely desirable.

The Effect of Ultraviolet Rays—The effect of ultraviolet rays on varying concentrations of the follicular hormone has been determined by Edgar Allen and M. M. Ellis, Columbia, Mo. (*Journal A. M. A.*). It was found that exposure to ultraviolet rays in air destroys both the ovarian hormone and the placental hormone, and further, that the action is on the hormones rather than on the oil used as a solvent. The positive test in a 1:3 dilution of the irradiated extract in the second series and the two indeterminate tests of irradiated residues in the third series indicate that the destruction of these hormones is gradual rather than sudden. This destruction of these hormones by the ultraviolet rays may possibly be associated with some oxidative change, as it is well known that ultraviolet rays promote the oxidation of some substances and also the molecular oxygen is partly transformed by ultraviolet rays into ozone.

Cholecystitis and Cholelithiasis in Young Children—Three cases of gallbladder disease in children under 10 years of age are reported by C. C. Snyder, Pasadena, Calif. (*Journal A. M. A.*). The children were aged 4, 5½ and 9½ years, respectively. The patients were operated on, and in each case drainage was followed by uneventful recovery. The preoperative diagnosis in these three cases was acute appendicitis.

THE PROSTATE AND ITS INFLUENCE ON LOW-BACK PAIN

By LIONEL P. PLAYER, M. D., *San Francisco*
(From the Department of Urology, University of California)

Until recently writers considered pain in the back due entirely to static conditions, muscle or ligament strain, and nerve involvement, excluding arthritis patients.

Eradicating the focal infection of the prostate and seminal vesicles, as well as the tonsils, teeth, adenoids, appendix, etc., will cure cases of myalgia, myositis, synovitis, and neuritis.

Orthopedic surgeons find in backache associated with prostatitis, x-ray lesions of the pelvic joints in an average of 25 per cent of patients.

One of the most important causes of backache in man is prostatitis. Routine examination of the prostate should be made in all male patients complaining of backache, and, if involved, proper treatment given.

DISCUSSION by Fraser L. Macpherson, C. P. Mathe, George J. McChesney, H. H. Markel, *San Francisco*.

IN CONSIDERING the subject of the prostate and its influence on low-back pain, one must bear in mind the intimate relationship of the prostate and seminal vesicles. I voice the opinion of other investigators when in stating that prostatitis and seminal vesiculitis almost invariably occur together, and so I will consider them as a unit.

Backache is a common complaint, and patients usually seek relief at the hands of the physician or the orthopedic surgeon. If less enlightened, but influenced by glaring advertisements, they may take treatment from an osteopath or chiropractor.

The urologist sees these patients frequently when urological symptoms are uppermost (on many occasions in the clinic particularly, back pain has erroneously been called kidney pain by the patient) and backache not so prominent, but usually in consultation with the family physician or the orthopedic surgeon who is endeavoring to discover a focus of infection which may be the etiological factor in sacro-iliac or lumbo-sacral joint inflammation. I am not assuming that prostatitis is the sole factor in backache, because such localized pain may be the result of foci elsewhere. I am positive that backache does exist, however, when inflammation of the prostate is the only discoverable site of infection.

I am purposely excluding tuberculosis of the spine or genito-urinary system, lues, malignancy, organic nervous diseases, and fractures of the spine or joints under discussion. Acute gonorrhea is also excluded, since in the acute stage this disease shows a predilection for other joints primarily.

In the past three years I have incorporated the question of backache in taking routine urological histories, and this paper is based on one hundred such histories—our findings and treatment in these chronic cases.

It may be well to mention here that female low backache may be due to pyelitis, ureteritis, cystitis, trigonitis, urethritis, urethral stricture, or polypos—exclusive of or with pelvic inflammatory conditions. Treatment directed to such conditions, exclusive of pelvic inflammatory disease, will often relieve backache if they are the only foci existing.

The question of accompanying foci in the sinuses,

teeth, tonsils, is highly important, for, in looking over a large number of histories, it was evident that, unless all possible foci were treated along with prostatitis, improvement was slow and recurrence the rule.

Some authors disregard or fail to mention focal infection as a cause of backache. Others discussed this symptom before focal infection was considered a factor. Robert W. Lovett omits purposely tuberculosis of the spine, organic nervous diseases and spinal fractures in his paper on "Backache and Prostatitis," and considers three etiological possibilities:

1. Disease or displacement of joints.
2. Traumatism to the back.
3. Arthritis of the spine.

He also adds two more classes which cover forty-one out of eighty-three of his cases:

A. Static in origin, due to overstrain of posterior musculature and pain due to irritation of muscles, ligaments, and fasciae.

B. Special strain or relaxation of sacro-iliac joints.

The static A type he says is caused by forward displacement of center of gravity with undue strain on posterior muscles, which causes pain in these muscles and fasciae. As a result of this forward displacement the author admits of strain on sacro-iliac joint, but thinks the pain is in the muscles and fasciae and not in the joint. Lovett refers to Roland O. Meisenbach's article (2), in which this investigator attempts to prove that the sacro-iliac joint is a true joint and reports eighty-four pathological conditions. This paper preceded any work on focal infection. In his cases of sacro-iliac relaxation he classifies the following types: traumatic, general debility, uterine, neurotic. He claims in pregnancy that the sacro-iliac synchondrosis yields and admits motion. He with Dr. Albee proved, by injecting methylene blue in the joints of cadavers, that it is a true joint and has all the anatomical structures, i. e., hyaline cartilage, synovial membrane, and supporting ligaments. One of the chief reasons for relaxation of this joint is that the sacrum may be so pulled out of place in its articulation with the ilium that there is a pressure on the nerves, with resulting sciatica. Also undue forward position of the body with a relaxed joint would keep it pulled out of place and produce pain in that region. If this is taken into consideration, together with focal infections in the pelvic viscera, prostate seminal vesicles, and elsewhere, one can understand why, with a synovitis developed, there would be pain in the sacro-iliac or even the lumbo-sacral joints, especially when one is familiar with the selective action of bacteria as described by Rosenow. Lovett denies that there is any evidence to prove slipping of the sacro-iliac joint or pain caused by this joint condition either with the x-ray, by palpation, or post mortem, as described by Meisenbach. He says: "In my series of eighty-three cases I have failed to find evidence of slipping, displacement, or abnormal motion." He lays stress on the static A theory with defective antero-posterior balance. Of backache of pelvic origin, he says: "In general, pelvic backache is sacral but may be dorsal,

and is generally associated with symptoms pointing to pelvic disturbance." He still adheres to his pet theory that even pelvic backache is caused by forward bent position above mentioned. He accedes to the traumatic type (2), and regarding the arthritic type (3) he considers nerve-root pressure, mentioning stiffness and lateral deviation of the spine, and x-ray evidence of the presence of osteophytes in the vertebrae, and lipping of the vertebrae edges. With such x-ray evidence today we seek a focus of infection and consider the rest of it postural.

Frank Billings, besides mentioning the mouth, faucial tonsils, and sinuses as sites of chronic focal infection, also mentions the prostate, seminal vesicles, and female genitalia. The bacteria he cultured were streptococcus viridans, and streptococcus hemolyticus pyogenes. He quotes Rosenow, who found that the principal types of infection in the joints, etc., were those that occupy a position between streptococcus viridans and streptococcus hemolyticus. They are more virulent than the former and less virulent than the latter. Injected into rabbits they produce arthritis, endocarditis, myocarditis, and pericarditis. He advises the removal of all sources of infection, and mentions especially treatment of the prostate gland and seminal vesicles. He recommends autogenous vaccine and vasotomy to drain and wash out the seminal vesicles. Hugh Young calls attention to the limited recognition of the genito-urinary tract as a focal site in many vague pains. He lays especial emphasis on the fact that chronic diseases in this tract may exist for years without symptoms, but such infections, with their toxins in the prostate and seminal vesicles, irritate the nerve terminals of these organs, sending stimuli to other viscera and superficial regions, according to the dicta laid down by Head. He says, "I have often seen cases of lumbago, sciatica, vague pains in hips, thighs, perineum, groin, and as far as the sole of the feet, due to it," and recommends in extreme cases, perineal prostatectomy as a means of relief. He also quotes Fuller's article on seminal vesiculotomy, with report of cases and 50 per cent cures in arthritis. Brandsford Lewis, in discussing Young's paper, brings out the following points: Ninety per cent acute anterior urethritis cases become posterior, and mentions Young's operation in extreme cases. Gotlieb brings out the fact that the subject of chronic backache is casually mentioned in some textbooks. He quotes Keys: "Pain in the back in these cases is usually in the upper sacral region; it is a constant aching in character, uninfluenced by urination." Pearson: "Spondylo-arthritis is not an uncommon complication of gonorrheal diseases of the joints, and the sacro-iliac joint is involved sometimes." Guiteras mentions the possibility of gonorrheal arthritis of the sacro-iliac and inter-vertebral joints. Billings, Rosenow, and Adami state that the prostate and seminal vesicles are important sites of chronic infection. Gotlieb advises the proper fitting of shoes, correction of faulty statics, and treatment of the prostate for backache. Arthur P. Luff describes a condition which he terms fibrositis of various organs of the body. He mentions tonsillitis, pharyngitis, and absorption of toxins, but does not mention the pelvic organs. A. H. Swartz made cul-

tures in twenty cases of prostatitis. In 65 per cent the streptothrix was demonstrated either in pure culture or mixed with staphylococci. He made infected vaccines which gave good results in all but three cases, which required prostatic massage along with the vaccine. L. P. Player and C. P. Mathé, in a study of tumors of the vesicle neck and prostatic urethra and their relation to prostatitis, found that backache was a symptom in fifty-two of sixty-eight cases. Moses Behrend lists every cause of backache, with the exception of focal infection, in the pelvis. J. R. Caulk and H. G. Greditzer studied 300 cases of prostatitis and seminal vesiculitis; in 203 or 67.66 per cent of these cases they found referred pains or aches in the back (lumbago), legs and hips (sciatica), suprapubic region, groin, perineum, testicles, scrotum, penis, urethra, and kidneys. Of all these, however, lumbago and sciatica were most frequently mentioned. They regret the fact that the prostate and seminal vesicles are so frequently overlooked by the general practitioner as a possible source of infection and absorption of toxins in the production of vague and referred aches and pains, and say: "It is with this class of referred pains that our best results have often been obtained." Edward C. Rosenow and Winifred Ashby took material from infected foci in the human suffering with myalgia, myositis, arthritis, and peri-arthritis in one of their experimental groups and injected sixty-one animals; 79 per cent developed myositis and arthritis, 26 per cent had turbid fluid in the joints, none developed lesions in the nerves. In another group a small percentage did develop lesions in the nerves.

In a previous paper, Player, Lee-Brown, and Mathé published a table showing the results of cultures obtained from sterile secretions obtained from the posterior urethra taken directly from the prostate and ejaculatory ducts by a special instrument. The following is the table, and bears a close relationship to the findings of Frank Billings, who collected streptococcus viridans and streptococcus hemolyticus from the prostate and seminal vesicles. Rosenow found that the principal types of infection in the joints were those that occupied a position between the streptococcus viridans and the streptococcus hemolyticus. Why, then, should not prostates and seminal vesicles play a very important part in backache?

In a survey of 500 private and clinical urological histories, 60 per cent, or 300 cases, complained of pain in the back as an outstanding symptom. In 100 of these, taken at random, prostatitis and seminal vesiculitis were present in eighty instances. Of the eighty, sixty-one admitted gonorrheal infection, four

were or had been chronic masturbators, six had indulged in sexual excesses and were alcoholics. Three had been operated for hemorrhoids or fissures. The remaining six could attribute no cause. It is interesting to note that, in this group of cases, eight had been perfectly well until an attack of influenza; four had furunculosis; others blamed exposure to cold, overexercise, or strain. One had inserted wax tapers into the urethra and infected his bladder, urethra, and prostate. Other foci were present in fifty of this group of cases; the teeth were the disturbing element in thirty instances; infected tonsils, sinuses, and anal conditions were found in the remaining twenty. In the presence of other foci, prostatitis, and particularly seminal vesiculitis, is prone to recur, which fact emphasizes the importance of clearing up all focal infections. In the absence of foci elsewhere, the result of treatment of prostatitis and its influence on the back pain is quite gratifying, although, as a rule, patience on the part of the surgeon and the patients both is quite essential. Gradual improvement without recurrence of pain is not the rule. The secretions will show practically no pus at times and the pain be more pronounced. Conversely, the patient will be free of pain and secretions show more pus. When one remembers the histological structure of the prostate and seminal vesicles, the difficulty of emptying the numerous small abscessed acini by massage, the difficulty to effect a cure may be readily understood. The following table, No. 2, will assist in simplifying the findings in our 100 cases with backache as a pronounced symptom.

The other signs and symptoms in prostatitis and seminal vesiculitis are: shreds in the urine, moisture or watery discharge in the meatus, perineal discomfort, suprapubic pain, backache, arthritis, impotentia, sexual weakness, painful nocturnal erections, mental depression, neuroses, premature and painful ejaculation.

An analysis of the above table reveals the following data: Backache was most common in the third and fourth decades of life. Fifty-seven and three-tenths per cent of this group had only one gonorrheal infection. The onset of backache occurs most frequently between one and two years and two and four years following the last gonorrheal infection. Diagnosis in 70 per cent was prostatitis, seminal vesiculitis, and littritis. Urethral strictures, slight in extent or well developed, comprised 35 per cent. Urethral polypi or expressences occurred in 30 per cent. Urethritis and trigonitis are not constantly present, but do occur during the disease. Referred pains in joints were complained of as follows: Sacro-iliac, 30; lumbo-sacra, 20; sacro-iliac, lumbo-sacral, and hip, 41; shoulders, 4; knee, foot, wrist, elbow, ankle, 5. Wassermann test was positive in twenty-two cases. By massaging the glands of Littre on a urethral sound, gonococci were found within twenty-four hours in stained smears in seven cases. In one of these seven gonorrhea had been denied. Of the one hundred cases under consideration, seventy-five took treatment, thirteen requested diagnosis only, and twelve did not continue treatment after a few weeks. (Read off duration of treatment in Table II.)

There is one point in particular worthy of em-

TABLE II

Age	Gonococcus Number of Infections	Onset Present Illness Fol- lowing Last Neisser Infection	Diagnosis	Referred Pains	Treatment Kinds	Duration
Under 20 years 13	One attack 5	Under 1 month 0	Prostatitis, vesiculitis (seminal) 70	Sacro-iliac 30	Massage, stripping, dilatation, Vaccine, Anterior instillation 27	Three months 10

Results: The treatment of prostatitis alone when all other foci have been attended to is of prolonged duration, anywhere from three months to three years being the time allotted in my series of cases; the average case will clear up within a year. The influence of elimination of all foci on the backache is in proportion to the degree of infection remaining. Orthopedic care of static conditions and correction of faulty posture and shoes are essential to good results.

phasis in making routine examination of prostate and seminal vesicles as a possible focus of infection. No one can palpate a prostate per rectum and tell definitely from its size, shape, and consistency whether or not infection is present. It is often necessary to massage the prostate and strip the vesicles from one to four times on consecutive days before the secretion will show in its true light.

Early in this article I mentioned that a great many patients complaining of backache and with prostatic and seminal vesicular involvement first seek aid of the orthopedic surgeon. In order to obtain definite data on the percentage of such cases I sent questionnaires to the orthopedic surgeons of the state, containing two questions: 1. "In what percentage of patients complaining of pain in the back associated with prostatitis do you find x-ray pathology in the lumbo-sacral and sacro-iliac joints?" 2. "In what percentage of patients complaining of pain in the back do you find prostatitis?" I have received sixteen replies. I may divide these answers into two classes: First, those who have definite figures at hand and can answer the questions in terms of percentages, and second, those who, though giving an affirmative answer to both questions, are unable to investigate their case histories in order to obtain the exact data and give definite figures. In the latter class: A admits percentage in questions 1 and 2, but has not completed his card index system and cannot give exact figures. B admits a certain percentage in questions 1 and 2, but impossible to give exact figures. C admits a certain percentage of cases in answer to both questions, but does not know the figures. D: "I cannot give the percentage, but do not think it to be very large." E: "I do not see

enough patients complaining of pain in the back associated with prostatitis to give a helpful answer in terms of percentage." F: "Have no figures of any value." G: "Have not had any cases of prostatitis referred to me with back pain." H, answering No. 1, says: "In chronic cases practically all." Answering question 2, "I am unable to say, but a small per cent." I, answering question 1, "I do not know." Answering question 2, "A small percentage." Now I have just presented the answers from nine correspondents, and they present no definite figures. From seven other orthopedic surgeons who have definite percentages to offer, I received the following data:

1.	Answer to question 1—5 per cent.
"	" " " 2—10 to 15 per cent.
2.	" " " 1—10 to 20 per cent.
"	" " " 2—20 per cent.
3.	" " " 1—Has no statistics.
"	" " " 2—30 per cent.
4.	" " " 1—Between 30 and 40 per cent.
"	" " " 2—Not over 10 per cent.
5.	" " " 1—30 per cent.
"	" " " 2—30 per cent.
*6.	" " " 1—50 per cent.
"	" " " 2—60 per cent.
*7.	" " " 1—25 to 50 per cent.
"	" " " 2—50 to 75 per cent.

To sum up these answers I note that all of the sixteen representative orthopedic surgeons of this state admit they find x-ray pathology in the lumbo-

*Data taken from histories in both clinic and private patients after careful survey.

sacral and sacro-iliac joints in patients complaining of pain in the back associated with prostatitis. Also in patients complaining of pain in the back they find various percentages of them suffering with prostatitis. Nine of the doctors do not offer any definite figures, whereas seven give definite percentages to both questions. To the six answers in question 1 of this group, I find that the average is 28 per cent, or, in other words, that among thousands of cases treated by these orthopedic surgeons they find among the prostatitis with pain in the back definite x-ray lesions of the lumbo-sacral and sacro-iliac joints in twenty-eight out of every one hundred cases. The seven answers to question 2 of this group averaged 32 per cent, which means that, of patients complaining of pain in the back, thirty-two out of every one hundred have prostatitis. Though the average percentage in the answers to questions 1 and 2 are 28 and 32 per cent, respectively, yet I note that some of the surgeons report much higher figures, from 50 per cent to even 75 per cent. These percentages of joint affections with prostatitis are remarkable when we take into consideration the fact, following the researches of Rosenow, that the selective action of the various types of streptococci emanating from the various foci of infection may have a predilection for the tendon sheaths, muscles, and joints, and that in very mild involvement of the joints, as well as in even severe infection of the back muscles with their tendons, they may very often show no definite lesions on the x-ray plate. Thus, in many cases there may exist definite involvement of the muscles, tendons, and joints of the back attributable to bacteria from prostatic foci without any demonstrable lesions.

DIAGNOSIS

All patients should have general examination by someone capable, who should refer them to proper specialists. Specialists cannot be efficient in general examination. Our investigation includes: Urine, complete chemical and bacterial examination. With the patient showing definite chronic complications, urine is drawn from the bladder with sterile precautions for culture and inoculation of guinea pigs; careful examinations per rectum and charting of the prostate and seminal vesicles, Cabot test, microscopical, cultural examination of massaged secretions; examination of urethra and bladder with urethroscope and cystoscope, charting the findings if necessary; catheterizing the ureters and taking x-ray pictures of the whole tract, including kidneys, ureters, bladder, and other organs of the pelvis to discover abnormalities.

TREATMENT

Non-surgical—Seventy-five patients were treated in the routine manner by massaging the prostate, stripping the seminal vesicles, sounds, instillations. Five of these received vas injections. Thirty received, in addition to regular treatment, intermuscular injections of autogenous and stock vaccines. The influence of the vaccine on the pus content of the prostate and seminal vesicle secretions was disappointing, but the backache was relieved entirely in approximately 22 per cent. Mixed vaccine rich in gonococci, given during the acute stage of gonorrhea, reduces the percentage of complications in the

prostate, seminal vesicles, and epididymi. The majority of these patients were under treatment by the orthopedic and general surgeons for static conditions, painful joints and foot defects, etc. The few cases that were not under the orthopedic care were not relieved of back pain until the secretions were much improved. In our opinion good results in backache with prostatitis depend upon co-operation between consultant, the surgeon handling the case, and the patient. Other factors that influence the results obtained are assurance that the ejaculatory and prostatic ducts are patent, dilation of strictures, emptying and cleaning the glands of Littre, destruction of polypi, eradication of infections and inflammations elsewhere in the genito-urinary tract along with distant foci. The general physical condition of the patient must be considered; hygiene, diet, tonics are indicated in nearly all cases. Injections of various antiseptics intravenously are being tried, with reported good results.

Surgical—Vas injection, according to the dictates of Belfield, and modifications of the same idea are of great assistance in some of the resistant types. Fuller advises in extreme cases seminal vesiculectomy or seminal vesiculotomy, and reports 50 per cent are cured. O. S. Lowsley reports ten surgical cases representing 29.6 per cent, two vesiculotomy, eight vesiculectomy, with good results in three, fair in six, poor in one. Young advises his perineal prostatectomy. In the five cases in which we performed vas injection, good results were obtained in four. The other cases did not respond. His arthritis is growing steadily worse and will probably require radical operation.

The onset of backache occurs most frequently between one and two years and two and four years following gonorrheal infection. Diagnosis in 70 per cent of cases was prostatitis and seminal vesiculitis; in 30 per cent prostatitis, seminal vesiculitis, and lithtritis. Urethral strictures, either slight or well developed, in 35 per cent; polypi, polypoid masses, and excrescences occurred in 30 per cent; urethritis and trigonitis existed at intervals during the disease.

I wish to express my thanks to Dr. Redewell of the University of California for his assistance in preparing abstracts.

SUMMARY

1. Until recently writers considered pain in the back due entirely to static conditions, muscle or ligament strain, and nerve involvement—excluding arthritis patients.
2. Rosenow and his followers have shown that bacteria from foci of infection have selective action and the different types produce myositis, myalgia, synovitis, and arthritis.
3. Eradicating the focal infection of the prostate and seminal vesicles, as well as the tonsils, teeth, adenoids, appendix, etc., will cure cases of myalgia, myositis, synovitis, and neuritis.
4. We have in prostatitis analogous organisms to those reported by Rosenow in other foci.
5. Orthopedic surgeons find in backache associated with prostatitis, x-ray lesions of the pelvic joints in an average of 25 per cent of patients.

6. Only by taking complete histories and making careful diagnoses can prostatitis patients with backache be properly treated.

7. In treating prostatitis all contiguous organs must be carefully looked after, in order to eradicate all possible foci of infection, i. e.: seminal vesicles, bladder, kidneys, ureters, vas deferentia, epididymii, urethra.

8. One of the most important causes of backache in man is prostatitis. Routine examination of the prostate should be made in all male patients complaining of backache, and, if involved, proper treatment given.

9. There is no specific cure for chronic prostatitis, and the fact that it takes from months to years of careful treatment to eradicate inflammation in that gland, we must believe that when we find such inflammation the cause of backache in so many patients, full relief will come only with co-operation between that wonderful bulwark of medicine, the general practitioner, the general and orthopedic surgeon, the urologist, and last, but most important of all, the patient himself.

380 Post Street.

DISCUSSION

FRASER L. MACPHERSON, M. D. (380 Post Street, San Francisco)—Dr. Player's paper is of extreme interest to me because I have had an opportunity to follow some of his patients from an orthopedic standpoint.

It is remarkable how fast low-back pain associated with prostatitis will clear up under urological treatment. One can usually be suspicious of a prostatitis if a patient complains of low-back pain not associated with any definite history of injury and on examination shows no list and refers pain to sacrum. Patients that do give a history of an injury and fail to get relief from good orthopedic treatment will usually be found to have a prostatitis. This is often true of many industrial cases which drag on indefinitely.

Prostatic examination is too often neglected by the profession because of its disagreeable feature. Even if it is done one is apt to be satisfied with one massage. As Dr. Player mentioned, it is necessary to massage three or four times on consecutive days in order to determine a prostatitis. Many doctors are willing to take a patient's denial of a Neisser rather than make an examination. These cases are the ones that usually show an infection, although many are non-specific in nature.

It should be a rule in every case of low-back pain showing x-ray changes to examine the prostate, just as we routinely examine the teeth and tonsils.

Having eliminated the prostate, teeth, and tonsils as foci of infection, the co-operation of the orthopedist is necessary to correct static faults, such as poor posture, short achilles, pronated feet, and weak musculature, in order to relieve a joint that has been injured through disease as well as strain.

C. P. MATHE, M. D. (Phelan Building, San Francisco)—Dr. Player emphasizes the fact that in 500 cases of prostatitis, 60 per cent complained of backache as their outstanding symptom. When sacro-iliac, lumbo-sacral, or hip pain is found associated with an urethral morning discharge, prostatitis should be strongly suspected.

In 1921 Player and I reported sixty-eight cases of chronic prostatitis and seminal vesiculitis complicated by polypi of the vesical neck and posterior urethra. In reviewing the sixty-eight cases we found that fifty-seven had pain and discomfort in perineum, fifty-two had dull lumbo-sacral pain (backache), twenty had inguinal pain, thirteen had hypogastric pain, fifty-two had repeated or constant morning drop.

We noted the fact that morning urethral drop occurs as frequently as the lower back pain. When both were

present the prostate was found infected in 99 per cent of the cases.

Many cases are overlooked due to an incomplete or incompetent examination of the prostate. The prostate must be examined four times by a competent urologist before a negative report can be reliably given. If no secretion is obtained the prostate should be massaged on a bladder in which sterile water has been introduced, the urine voided, then centrifuged, and examined for pus and organisms.

The co-operation of the patient is necessary in order to obtain relief. He must be assured that the treatment will be of long duration. Player shows that the average uncomplicated case of prostatitis usually clears up in less than a year. The complicated cases require longer time. In those whose resistance is good the length of time is shorter. I have observed that robust athletes clear up rather quickly, whereas 50 per cent of syphilitics show practically no improvement even after years of treatment.

The orthopedist well realized the importance of prostatitis as a possible cause of lower back pain. It is the general practitioner who sees large groups of patients that should be brought to realize that in at least 33 per cent the common complaint causing so much discomfort and suffering can be relieved by a careful examination and treatment of the prostate gland.

GEORGE J. MCCHESENEY, M. D. (Fitzhugh Building, San Francisco)—This article of Dr. Player's is a timely one in that it once more reminds us of the importance of focal infections in spinal arthritis, which we are too prone to neglect. This is shown by the rather sad results of the questionnaire to orthopedic surgeons, those results not being of such accuracy and unanimity as would indicate that the focal liability in prostatitis was receiving the proper attention it should from orthopedists. Personally I confess to being more or less delinquent, and for the following reasons:

As Player states, a proper urological opinion can only be obtained after three or four examinations. This makes an orthopedic surgeon's opinion concerning the prostate just as valueless as an orthopedic opinion on teeth or tonsils, but in the latter instances he can refer the patient to a dentist or a throat specialist and get an opinion as to the liability of focal infection at one interview, whereas in the case of an opinion concerning the prostate, in private practice one might hesitate in sending a patient for rather prolonged urological examination, unless the indications were strong as to the necessity for it.

The temptation is present to shirk one's responsibility, and it seems to me that if a method could be found to obtain a positive urological opinion at one interview it would be of great benefit to all concerned.

Of course, there may be serious cases that are admitted to hospitals where this objection does not qualify.

There can be no argument as to the soundness of Dr. Player's conclusions and the means by which he arrives at them.

H. H. MARKEL, M. D. (380 Post Street, San Francisco)—As presiding officer of this section on orthopedic surgery I am especially glad to hear Doctor Player's results. I am very sure that many, many cases of low backache are caused by prostatitis, and many cases of injury are aggravated and prolonged by it. Many physicians are satisfied with making a single examination, and when the secretion is found to contain little or no pus, to call it negative. But if such a case be re-examined two or three times an increasing amount of pus will be found, and as treatment is continued a still greater amount will be secured. I believe that it is most important that these low percentage cases receive proper treatment and not consider the pus found to be due to traumatism of the prostate, as some would have us believe. The papers in this symposium have been very gratifying to me, and the attendance has been very pleasing as well, showing the interest the subject has for all medical men.

DOCTOR PLAYER (closing)—I wish to express my thanks to those who have discussed the paper. It is gratifying to know that their opinions coincide very closely with my conclusions.

Dr. McChesney raised the question as to the possibility of a quicker method of diagnosing prostatitis. I agree

with him that it is oftentimes difficult for a patient to return to the office for massage on four consecutive days. It is also expensive for the patient, but I am sure any urologist would be only too glad to make a nominal fee according to the means of the patient.

The glass tests are not satisfactory in themselves and I know of no other means at present other than prostatic massage and microscopic study of the secretion obtained which will give us positive data. McChesney's suggestion, however, is worthy of consideration.

CONSIDERATION OF PROGRESSIVE MUSCULAR DYSTROPHY WITH PSEUDO-HYPERTROPHY FROM AN ENDOCRINE STANDPOINT

By CLIFFORD WRIGHT, M. D., Los Angeles

Dysfunction of the pituitary gland considered etiologically important.

Recent literature and clinical evidence commented upon.

DISCUSSED by H. Lisser, San Francisco; H. Douglas Eaton, Los Angeles; Edward N. Reed, Los Angeles.

WHEN the earlier investigators of progressive muscular dystrophy discovered that there was no evidence of pathology changes in the brain and central nervous system, it became necessary to look further for the etiology of this interesting, yet quite irregular group of muscle disturbances. That they are endocrinopathies, probably pluri-glandular, seems borne out by the frequent association with other glandular disturbances, as Grave's disease; Addison's disease; acromegaly; and myxedema, and that many cases show pigmentation; vitiligo; hypo-glycemia; asthenia, and many other endocrine symptoms. Several cases have shown spontaneous cure at puberty, probably through some action of the gonads or other endocrines.

The pituitary gland, particularly the anterior lobe, has a very marked effect on the skeletal growth; muscle development and the maintenance of muscle tone and any disturbance of these may depend on some pituitary condition. I have had a series of nineteen cases of progressive muscular dystrophy with pseudo-hypertrophy, and it is the association of these conditions with other symptoms of pituitary disease that will be considered here.

In the progressive muscular dystrophies due to the irregularity of muscle involvement, the course of the disease; the absence or presence of contractures and other factors, a classification suitable to all cases is not easy.

Erb's classification into hypertrophic and atrophic forms has been usually followed, but one specifying a rapid and slow type is quite practical. While usually the earlier the condition starts the more rapidly progressive it is, this is not always so. One of my untreated patients, 9 years old, who has been affected six years, is practically bedridden; one at 12 who has been sick since 3 years of age, and one 15 who has had paralysis since 2 years of age, show slower progress of the paralysis. Heredity must play a part in this disorder, for in some instances several generations of the same family have shown some form of the disease. In 1916, Timme of New York reported a series of fourteen cases extending through three generations in one family. Twice in my series two brothers were affected, and

Sella turcica in each instance smaller than normal.

the great-grandmother of another patient and her six sisters all developed the condition at about 50 years of age, and a daughter of one of these women was affected. Of my nineteen cases, twelve are boys and seven are girls.

The usual tendency of the disease is to progress to complete invalidism showing exacerbations lasting from one to several weeks, when the patient shows more active symptoms and frequently is bedridden. These increase in severity and duration, as well as frequency, and death often comes at 16 to 18 years in the earlier cases, while the slower cases continue on to old age. Death may be caused by some intercurrent condition or from involvement of the respiratory or cardiac centers.

SYMPTOMATOLOGY

At first it is noticed that the child is clumsy, falls frequently, and is unable to walk up or down stairs. Later the typical waddling gait appears, and after falling, the child, in rising, will crawl up its own legs. The legs are usually first affected and show the typical pseudo-hypertrophy of the calf muscles, with atrophy of the shoulder girdle. Knee-jerks are absent; the paralysis is irregular. In no cases have I seen facial involvement. One has atrophy of the thenar and hypothenar eminences. Atrophy usually follows the false hypertrophy. Contractures are frequent and varied. Those of the heel cord are most frequent and prevent standing in many cases; others are equinovarus; hamstring contractures and scoliosis. Microscopical muscle changes are splitting of the muscle fibers, proliferation of nuclei, proliferation with hyperplasia of vascular tissues and deposit of connective tissue and fat. Sometimes muscle fibers have entirely disappeared and the muscle becomes pale. The electrical reactions are normal. The sphincters are intact. Sensibility is intact, also the special senses. With these, and most interesting from my standpoint, are the following pituitary symptoms: Large, round head; round face; spaced

teeth; heavy central incisors; pituitary type of hand, smooth mottled skin, poor nails and sexual underdevelopment, all found in anterior lobe insufficiency and girdle obesity; high sugar tolerance; and weak pulse found in posterior lobe conditions. A large percentage of my patients were backward mentally. In addition, in most cases, x-rays show an undersized sella turcica and rarification of the bony tissues, both indicative of pituitary disturbances. These children always appear to be in good general health,

cluding bracing for support; prevention and correction of deformities and graduated muscle training and organotherapy. For several years I have used pituitary products by mouth and hypodermic. Whole gland powder is given by mouth, and when indicated pituitrin is given hypodermically, and occasionally adrenalin and small doses of thyroid have been used.

While I have had no complete cures, a large percentage of patients have been benefited to the extent

FIGURE 1

Showing round head, round face, and spaced teeth.

Undeveloped sexual organs; large calf; atrophy at the shoulder girdle, etc.

are happy, not constipated, rest well, and nearly all are voracious, indiscriminate eaters.

Case No. 1—This boy (see Figure 1) is 10 years of age. A younger brother has the same condition. Note underdeveloped sexual organs, large calf muscles with atrophy around the shoulders, large head, large round face, spaced teeth. This boy has the typical mottled skin and small, graceful, tapering fingers. The x-ray shows a sella turcica smaller than normal for this age, which is seen at the left. All the x-rays shown were taken with 24-inch plate tube distance. This makes the sella appear smaller than if taken closer. This different plate tube distance probably accounts for some of the discrepancies in tables of sella measurements. This patient has been under treatment three years and has made steady improvement, but is unable to stand at this time, due to contraction of the heel cords, for which his parents have not allowed operative procedure.

Case No. 2—This girl (see Figure 2) is 10 years of age, shows mild girdle obesity, the typical muscle condition, large head, large face, pituitary type of hands, and spaced teeth. X-ray shows small sella turcica.

TREATMENT

Includes general care—orthopedic supervision, in-

cluding bracing for support; prevention and correction of deformities and graduated muscle training and organotherapy. For several years I have used pituitary products by mouth and hypodermic. Whole gland powder is given by mouth, and when indicated pituitrin is given hypodermically, and occasionally adrenalin and small doses of thyroid have been used.

DISCUSSION

H. LISSER, M. D. (380 Post Street, San Francisco)—Doctor Wright deserves commendation for adding his observations and experience to the literature, which now contains many interesting records—metabolic, clinical, and pathological—which, taken together, suggest rather strongly an endocrine origin for progressive muscular dystrophy. The writings of McCrudden, McCrudden and Sargent (Janney, Goodhart and Isaacson), Timme, Boveri and von Werdt are especially worthy of review in this connection. As yet there is no agreement in assigning the primary causative role to any one ductless gland, some implicating the thyroid, others the pituitary, still

others the adrenals and pineal. In this uncertainty some writers prefer a discrete caution and consider the disease of pluriglandular origin. Although a coincidental affection of several glands is conceivable, it should be recognized that the great majority of endocrine diseases, of which we have any positive knowledge and which we are able to diagnose in life and verify at autopsy, are syndromes for which a single gland is primarily responsible and whose dysfunction clearly dominates the onset and subsequent course of the disease.

If further investigation should prove a uniglandular origin for this disease, I would venture to predict (in agreement with Wright) that the hypophysis will be

for several years. He has been working in a store about sixteen hours a day. This patient is by no means cured, but no one could question the veritable transformation in this man's appearance, strength, and vitality.

Since no measures other than orthopedic assistance are in any way beneficial for these unfortunate individuals, long-continued organotherapy is at least deserving of an adequate trial, and when more potent preparations are available, we may perhaps be rewarded by more striking and consistent success.

H. DOUGLAS EATON, M.D. (1136 West Sixth Street, Los Angeles)—It has been most interesting to read Doctor Wright's experiences with the use of pituitary medication

FIGURE 2
Shows spaced teeth, large round head, round face, and pituitary type of hand. Typical muscle condition, moderate degree of girdle obesity.

found primarily responsible. Hypopituitarism includes many of the phenomena characteristic of this disease—hypoglycemia, impairment in the power to store glycogen, adiposity, trophic changes in hair, skin, tendons, and nails; and, secondarily, genital infantilism with creatinuria, as is also found in eunuchoidism.

My personal experience in the glandular treatment of progressive muscular dystrophy is confined to one patient, and is, therefore, of little significance. This patient, nevertheless, has exhibited an amazing improvement, far and beyond what could be expected from the natural course of the disease. The malady is usually progressive, though sometimes stationary for a time; remissions are not noted. This patient has been observed for two and a half years. The treatment has consisted of whole gland pituitary extract by mouth and by injection (three injections a week) continuously administered since November, 1921. He has lost fifteen pounds in weight. He can raise himself on his toes, which he could never perform previously. He can walk upstairs, without climbing up his legs. Formerly he could not walk two miles; now he walks six to seven miles fishing. He can walk through the snow (lives in Truckee, California), which admittedly is a severe test for the weakened atrophied muscles of back, thighs, and legs. He was unable to control his hand in writing; he now can write for hours. Before he could not get up on his hands and knees in bed; he can do this easily now. He does not use a cane now; which he did

in progressive muscular dystrophy. If he has succeeded in arresting one case by its use, he has accomplished more than has been accomplished previously by any medication.

My experience with endocrine medication in progressive muscular dystrophy has been unsatisfactory up to date. I have been using pituitrin; the whole pituitary gland substance; and thyroid and adrenalin, alone and in various combinations, both by mouth and hypodermatically at the Children's Hospital for some years. I have attempted to suit the medication to individual indications, and have also tried using pituitary persistently, irrespective of definite evidence of hypopituitary function.

In looking for the explanation of my lack of success, I have felt that many of my patients were not pure types of dystrophy; many have shown changes in the reflexes and mental deficiency as well. I am planning to prove my diagnosis in the future, when possible, and restrict my endocrine experimentation to proved cases.

The other reason for my failure probably is, that pluriglandular dysfunction are present in progressive muscular dystrophy, and it is often difficult with present limited knowledge of endocrinology to determine the exact medication for a given case. Timme of New York, in a recent conversation with me, agrees in this hypothesis. Timme states he has had four cures in seventy-five cases, with a greater number of patients much improved as the result of pluriglandular medication. I also question

whether there may not be another important etiological factor as yet unrecognized.

We are indebted to Wright for presenting his interesting work, and emphasizing the hope that we may really learn to help such a distressing condition as progressive muscular dystrophy.

EDWARD N. REED, M.D. (2417 South Hope Street, Los Angeles)—I have observed a number of these cases at the Orthopedic Hospital School; and I have carried out with them the indications for prevention of deformities and for their correction when present. More than this, I have given them physiotherapy, baking, massage and muscle training, faithfully carried out over long periods of time, and proper bracing when indicated. I have learned that the best I could hope for was an arrest of the progress of the disease, apparently, in a certain number of patients—though for how long the arrest could be maintained I do not know. My experience has failed to show much, if any, improvement by physiotherapy and muscle training alone.

On the other hand, I can testify to the improvement in several of Wright's patients. These patients also had physiotherapy, muscle training, and bracing. But I feel that the results of Wright's treatment were very evident, in that with a number of the patients whom he treated showed demonstrable improvement.

DOCTOR WRIGHT (closing)—Doctor Lissner's patient was quite instructive, and it would seem, from the history, that if the case was not entirely cured it was benefited to the extent that the man was able to carry on his usual activities.

One of our patients, a girl, has been under treatment for six years, and while at first she had to be wheeled to and from school she now walks and is taking dancing lessons. This girl's mother declares that a cure has been effected; however, I feel that perhaps there is still some muscle weakness.

As Doctor Reed has said, orthopedic measures alone have failed to greatly benefit these patients, but those who have had orthopedic treatment plus organotherapy have shown beneficial results.

Arsenic Poisoning—Twenty-eight cases of arsenic poisoning are reported by G. B. Lawson, W. P. Jackson and G. S. Cattanch, Roanoke, Va. (Journal A. M. A.). Large quantities of arsenic were demonstrated to be present in cider which had been served at the noon meal. It was later learned that the barrel had contained an arsenic compound used for spraying trees. Thirteen of these patients died, the first death occurring in six hours, and the thirteenth on the thirteenth day after the taking of the poison. Ten of these deaths occurred in the acute stage, and the other three during the subacute stage, into which the patients had passed with a cessation of the acute symptoms on the second day. Immediately following the onset, vigorous supportive and symptomatic treatment was given; and nine patients, all of whom survived, repeatedly lavaged their own stomachs with warm water. After the Marsh test had demonstrated an abundance of arsenic, it was decided to use sodium thiosulphate with the hope of inactivating the remaining arsenic by the production of its nontoxic, insoluble sulphid. No immediate improvement was observed following the use of sodium thiosulphate. To be of possible value in acute poisoning, it should be given at once and in maximum doses. Analysis of samples taken at the time of the poisoning showed the presence of 3.38 grains of arsenic (As_2O_3) per fluidounce. Most of the patients drank several glasses of the cider, but because of the vomiting and diarrhea it was impossible to determine the amount retained.

Sinusitis and Swimming—H. M. Taylor, Jacksonville, Fla. (Journal A. M. A.), points out the modifications which the aquatic animals have for their environment and the striking absence of such adaptations in man. Man is essentially a terrestrial being, and his anatomy and physiology are not modified for a water environment. When man is out of his normal sphere he must understand what limitations Nature has placed on him, and not ignore the fundamental laws that regulate his own being.

THE TREATMENT OF EARLY CARCINOMA OF THE UTERUS

By J. W. SHERRICK, M. D., Oakland

Treatment of early carcinoma of the uterus implies an early diagnosis, detailed knowledge of the histologic picture, its gross and macroscopic characteristics, its methods of spread and the clinical course.

DISCUSSION by William H. Gilbert, Los Angeles; A. J. Lartigau, San Francisco.

MY CONCLUSIONS are based on a careful summing up and weighing of the opinions advanced by different authorities, who, from their experience and the clinical material at hand, may speak with conviction. Owing to the mass of literature on this subject and the necessarily divergent opinions expressed, it is impossible to quote extensively to prove the points under consideration. But from an unbiased study, aided by personal experience, I have reached the views as set forth and feel that they represent the consensus of current opinion of surgeons and gynecologists.

One of the most important and puzzling questions facing physicians is the treatment of early carcinoma of the uterus because of the prevalence of the disease, its poor prognosis and the problem of early diagnosis. Our task would be relatively easy if we could be assured that the patient would report when the disease is in its early stages, for then the line of procedure is fairly clear with a high percentage of cures resulting. But the very nature of this condition militates against an early diagnosis and adds enormously to our responsibility and burden. Speaking generally, it seems that from the vast detail of therapeutic measures that have been utilized from time to time, two procedures stand out as most rational, namely, radical operation and radium and deep x-ray therapy.

In carcinoma we are dealing with a distinctly local affection in the early stages, a parasitic epithelial new growth which is capable of growing without limit to infiltrate and destroy the tissues in which it originates and of spreading beyond the anatomical bounds of these organs to hematogenous and lymphogenous metastases in other parts of the body. It is capable of perpetual proliferation, its cells multiply without purpose or effect, and may remain latent in the host's tissues for years. It may exhibit cyclical changes with periods of rapid or of slow growth or even of retrogression. Its susceptibility to extraneous influences and its histologic structure vary from time to time. It presents no specific toxins nor does the organism react to form antibodies, but in the early stages it apparently may call forth an increased metabolism in the host's organs with later a failure to respond to this stimulus, at which time the cancer begins to live at the expense of the host.

Thirty per cent of cancer in women occurs in the uterus. Histologically uterine cancers, while having certain points in common, have not a fixed and unvarying structure. Each individual tumor presents its own particular characteristics with varying degrees of malignancy and within limits of varying susceptibility to therapeutic efforts. But clinically, there is no distinct difference in its varying forms, structure and location. For purposes of treatment,

we must deal with two broad classes, cervical carcinoma and corporeal carcinoma.

Treatment of early carcinoma of the uterus implies an early diagnosis, detailed knowledge of the histologic picture, its gross and macroscopic characteristics, its method of spread and the clinical course. Appreciation of the macroscopic picture is, in the minds of many, more important from a prognostic and therapeutic standpoint than knowledge of the microscopic appearance. This is true because we are learning that more and more must we depend on our visual and tactile sense, aided by careful clinical history and symptoms, in arriving at a working diagnosis which will permit prompt and efficient treatment. Yet a knowledge of the finer structure seems also necessary to enable us to place the tumor from a prognostic and therapeutic standpoint. I refer to such questions as the exact seat of the primary growth, the natural resistance of the immediate and surrounding tissues, the histologic makeup of the tumor, its growth characteristics; for upon these will depend its type and rate of spread, its tendency to metastasize early and extensively, or not. In carcinoma of the cervix there are two main types, squamous, or solid alveolar carcinoma, and adenocarcinoma. While there is no characteristic difference in incidence, symptomatology, physical signs, course or complications between the two forms, yet the type of spread and the stage of metastasis varies and adds materially to the prognosis and treatableness of the condition. Cancer of the uterine body is usually of the adenocarcinoma type. Rarer forms of malignancy will not be discussed.

Cancer cells, through a biochemical stimulus, cause angioplastic reactions in surrounding connective tissue, but the epithelial growth is disproportionate, resulting in infoldings of the surface and pressure and flattening of nearby soft tissues. Growth proceeds in all directions, being favored by diminished pressure and good nutritive conditions, and infiltrates and permeates surrounding tissue by pushing into the natural interstices, especially the lymph spaces, which are devoid of endothelial lining; thence into the lymph vessels along which it advances freely. By infiltration and lymphatic permeation process it extends into the cervical wall, upward toward the uterine body, outward toward the parametrial connective tissue and along the surface to the vaginal wall. Naturally, cancer beginning in the cervical canal will more quickly involve the parametrial connective tissue and lymphatics than cancer beginning on the vaginal portion. The spread, then, is by continuity, by the lymphatic system direct, or as secondary nodules or emboli, and by the blood stream. Involvement of the pelvic connective tissue occurs comparatively early in the form of discreet nodules, 75 per cent of the operative cases presenting this complication. More extensive involvement of neighboring tissues, such as the bladder and rectum, with marked ureteral complications, hydronephrosis, pyonephrosis, etc., need not concern us here, as it is a late picture.

The uterine, cervical and vaginal lymphatic drainage systems are of prime importance in the question under consideration. These structures present a freely communicating and continuous capillary network which gives rise to connecting

trunks that follow the course of the blood vessels to converge at the sides of the uterine isthmus and cervix. Collecting trunks from the cervix run outward along the course of the uterine artery to empty into external iliac glands near the obturator foramen. Some pass behind and below the ureter and up and outward to the internal iliac nodes; others pass along the sacrouterine folds to the nodes of the sacrum and promontory. Those of the lower body drain into the external iliac nodes along with the cervical chain, while those from the fundus proper follow along the course of the ovarian vessels to empty into lumbar nodes just below the hilus of the kidney. A few follow the course of the round ligaments to the upper group of superficial inguinal nodes. The most important groups of nodes, because of the frequency and the stage of involvement, are the interiliac situated between the internal and external iliac arteries and along the common iliac artery. The uterine lymphatics diminish very materially with establishment of the menopause, which is of importance, in explaining the rate and extent of metastases. The frequency of gland involvement and the groups involved are very inconstant. In one series, 28 per cent of women dead from cancer showed no gland involvement; 33 per cent of operated cases showed carcinoma of the glands, and 33 per cent enlarged glands, but the involvement was inflammatory with no carcinomatous glands present.

With these facts in mind we are in a position to consider the treatment of early uterine carcinoma. On superficial examination it would seem a question that is easily answered, i.e., radical removal in the early stage with the borderline cases presenting the real problem. Unfortunately, it is far from being such a simple problem. Because of its insidious development and the absence of outstanding symptoms early, too frequently the disease is quite extensive before it is discovered or even suspected. To this must be added the unfortunate fact that through modesty, unreasoning fear of the condition, or ignorance, which attributes the symptoms to the menopause, piles, etc., the patient often waits for months (average 6 to 11) before seeking advice. Furthermore, too frequently there exists carelessness, or inadequate experience on the part of the attending physician. These factors then suggest the difficulties encountered but offer no solution of the problem. I have no wish to outline any special plan for working out this question. Various methods of procedure are in use in the different states under the direction of the Society for Cancer Control, which yearly carries on a campaign of publicity, including clinics, lectures, newspaper propaganda, etc. This work has been admirable in the instruction and sound advice given forth with its slow leavening influence, but, after all, the crux of the problem rests with the physician.

It seems wholly unnecessary to even mention symptoms, but we are too prone to overlook the patient's statement that she has noticed a leucorrhœal discharge as an entirely new symptom or an altered amount and character of leucorrhœa previously present. This at first is of a watery, serous nature, somewhat irritating and becoming altered later to yellow, brown, green, bloody and foul as bacterial

invasion and ulceration occur. More frequently the first symptom complained of by two-thirds of these cases is hemorrhage, i.e., post-menopausal bleeding or an alteration in the character of the menstrual flow such as increased duration and amount of flow, increased frequency, irregularity of flow, etc., associated with trauma often. Frequently slight bleeding is completely overlooked by a large percentage of women. Pain, loss in weight and strength, cachexia, are all late symptoms and need not concern us here.

Since there are then no outstanding early symptoms, and because so often the patient's general condition early is improved, we must depend on education and our own conscientious efforts to arrive at an early diagnosis. This demands intelligent attention to details, experience in the different types of cervical lesions, frequent observation and study in every doubtful case, including inspection, palpation for any enlargement, swelling, growth, irregularity, suspicious induration, loss of elasticity, friability, parametrial and ligamentous thickening and resistance, etc. I would emphasize especially the macroscopic and clinical picture but in case of doubt the curet or a biopsy must be resorted to and submitted to the pathologist for study, preferably by frozen section method with preparations complete for immediate operation, if a positive diagnosis is returned. This eliminates the increased danger of hematogenous, lymphogenous and implantation metastases arising from the cut surface. I cannot subscribe to the view that every suspicious case should be subjected to operation or radium on suspicion alone. By careful study and intelligent observation of patients we can arrive at a diagnosis. Cases that present no difficulties in diagnosis offer little hope of cure as a rule. A good working rule is to consider every suspicious case as carcinoma until proved otherwise.

I believe that the treatment of early carcinoma of the cervix should be by radical operation where no contraindicating factors exist. The percentage of operability and of what constitutes an operable case varies in different hands, being from 40 per cent to 60 per cent and depending on the stage of the disease when first seen, and the skill of the operator. Operability means curability and implies early diagnosis. The proportion of surgical cures, i.e., freedom from recurrence after five years, varies from 40 per cent to 50 per cent plus, and the absolute curability of cervical cancer derived from a study of the total number of cases varies from 16 per cent to 25 per cent. These percentages are gradually being increased by improvement in technique and surgical judgment, by early diagnosis and all that it implies, and by the judicious use of x-ray and radium as post-operative measures. Surgical treatment demands great care in the choice of patients and an accurate knowledge of the origin and spread of the disease, of its local character early and at the time of the contemplated treatment, of its permeation of lymphatics and surrounding connective tissue, and of the lymphatic drainage system. It means wide removal of the common avenues of extension, including the upper vaginal cuff, the tubes, the ovaries, the broad ligaments, the parametria, the iliac and sacral lymph glands, etc. It means intelligent consideration of contraindicating

factors such as heart, kidney and tuberculosis. In 60 per cent of the patients deemed operable cancer has extended beyond the uterus and the actual condition of the parametrium and lymph glands cannot be determined by clinical examination. Conflicting statistical reports exist as to the results in general and as to the percentage of gland involvement remaining after operation as they include every type of case, many of which were hopeless. Glands are involved in from 30 per cent to 50 per cent of the early or operable cases. Surgically, the disease should be considered hopeless if it extends beyond the parametria, but the mere technical difficulties offered by radical surgery are no excuse for failure to employ it because of what it offers in the hope of cure. Limited surgery is useless.

The field for radium is indeed broad, including the inoperable and questionable borderline conditions, but its real field in early cases is not sufficiently tried and proved to warrant the throwing aside of surgery in early and operable cases. On the one hand we have carefully worked-over statistics gathered from thousands of patients treated by radical operation during the past twenty years and the ground is well outlined. On the other hand, radium *intelligently* applied, is too recent to permit of similar statements drawn from sufficiently large series to meet these requirements. We do not know what the years may bring forth in these radiated cases. Moreover, there is great uncertainty in radium technique, with constant changing and as yet no standardized outline of treatment has been developed. The pendulum at present seems to be swinging back from the massive primary dose of radium to the fractional small dosage with a large number of radiologists following no special system but laying primary emphasis on proper screening. Theoretically, radium seems an ideal therapeutic weapon with which to attack cervical carcinoma, since it can be inserted into the center of the malignant mass with resulting radiation of the pelvic tissues within a radius of six centimeters. Practically radium in ordinary dosage has power probably to kill only cancer cells lying within a radius of two to three centimeters. Beyond this distance the rays may be so weak as to stimulate cancer cells without destroying them. The close proximity of the bladder, ureters and rectum (2 cm. at best) render them subject to severe injury. While it is theoretically possible by supplementary cross-firing through different portals of entry to attack the parametrial wings and gland areas with the longer gamma rays, this requires such enormous doses of radium that it is removed from the realm of practicality. Moreover, radium, especially in unskilled hands, possesses vicious and annoying possibilities, namely, proctitis, nausea and vomiting, obstructing fibrosis with pinching of nerve trunks, general systemic reaction, fistula, etc.

The general systemic reaction with lowered resistance and predisposing to infection and intercurrent disease, the particular cell reaction and the general blood reaction are factors that we know little about. Other problems are measurement of dosage, standardization, ionization and osmotic changes in cells and fluids, effects on basal metabolism, the role of the cell lipoids and cell decay products, methods best calculated to stimulate the

patient's immunity, etc. Further, the expense of radium, the relative shortage of supply in some countries, the expense of installing proper x-ray apparatus, as well as the question of intelligent technique, necessarily limit the usefulness of this method. These, with other problems, must be cleared up before we can hope through comparative statistics to appreciate the limitations and possibilities of radiation. There is the additional factor of prolonged treatment which many patients will not follow to the end, and the fear of a recurrence in organs that have not been eradicated. The argument that recurrences following radium treatment will occur during the first year, if at all, does not hold, as shown by Bumm. We are all anxious to cure and in spite of a 10 per cent to 30 per cent surgical mortality, with the recent results pointing more and more to the lower figures, the results as yet justify operation in the early case of cervical carcinoma. The fact remains that about 50 per cent of operable carcinomas of the cervix may be permanently cured by surgery. According to Bumm's studies, the percentage of cures in operable and borderline cases of carcinoma of the cervix is one-third less with radiation than that obtained by operation at the end of six years, although reports exist from a few German clinics, Deoderlain, Seitz and Zweifel, with a claim for results with radium that equal those obtained by operation.

In borderline cases surgery offers only a 10 per cent to 15 per cent chance of cure and radium is, therefore, the treatment of choice, Bumm showing a 23 per cent five-year cure, 19 per cent four to five-year cure, and 39 per cent three to four-year cure. Perhaps in time, with improved radium technique, this may replace surgery even in the early cases.

Radium is a very questionable agent as a pre-operative prophylactic measure in operable cases or to render borderline cases operable. It increases the difficulties of operation, may give rise to septic complications, cannot reach the limits that surgery can, may stimulate outlying cancer cells, devitalizes normal tissues and renders them more susceptible to sepsis and possesses no special advantage as a preliminary "cleansing" measure over judicious cauterization (Graves). When it is used, surgery should follow within a period of three weeks.

As a post operative measure where there is a reasonable doubt that all of the diseased tissue has been removed, radium or deep x-ray therapy should be used as soon as the tissues have healed. Otherwise it possesses the dangers as above outlined, enhanced by the thinness of the tissues remaining, and exposing vital structures to radium burns. The judicious use of deep x-ray therapy as a post-operative measure would seem to offer more than radium, especially where the pelvic wings are to be treated. This avoids the dangers offered by radium in scar tissue and in organs such as bladder and rectum. Early cases rendered inoperable by such contraindications as renal disease, old age, obesity, diabetes, heart disease, etc., should be treated with radium.

In Graves' opinion, borderline cases are usually incurable by either operation or radium, but exploratory incision is justifiable with radium being

less dangerous and offering better chances for prolongation and comfort of life in cases of doubt.

Deep x-ray therapy as a primary procedure in pelvic malignancy is not rational, but may be used to advantage in cross-fire. To destroy cancer cells in the pelvis requires several portals of entry with deep therapy technique and in the presence of metastases there should be more to allow of thorough treatment of the various fields. This entails dangerous effects on the intestine, skin, bladder and is both time-consuming and expensive.

In cases of early carcinoma of the body of the uterus, surgery offers by far the greatest chance for cure. These conclusions are based on the type of lesion usually present, the usual advanced age of the patient with firm uterine walls, its relatively less malignant character, its slower spread with late involvement of the peritoneum and parametrium and late metastatic complications. Its operability is high (90 per cent plus) and final results are good with 51 per cent of five-year cures.

The following points in surgical technique should be emphasized: Cases for operation should be selected with the greatest care, an exploratory incision being resorted to in case of doubt. This procedure requires skill, careful technique and courage to proceed or even to desist where conditions seem to warrant. A careful cystoscopic examination of the bladder base is essential. Thorough cauterization of the cervix should be done immediately preceding operation and followed by tight suturing of the external os to prevent contamination of the operative area. This, aided by thorough sterilization of the vaginal canal with idodin, adds materially to the success of the operation. Some prefer radiation ten days to two weeks previous, but done without anesthesia, as these patients do not tolerate well a second anesthetic. The abdominal route offers a far better avenue of approach and greater opportunity for wide removal of the involved structures. A careful, systematic technique, based on exact anatomical knowledge, operative experience and skill and sound surgical judgment, should be followed.

350 Twenty-ninth Street, Oakland.

DISCUSSION

WILLIAM HENRY GILBERT, M. D. (Brockman Building, Los Angeles)—Cancer of the uterus is a subject so big and so full of important situations that it is very hard in the short space allotted one to cover the entire field. Dr. Sherrick's paper has so thoroughly covered the entire field that it is hard to find a point of entrance in order to intelligently bring out anything that he has not touched upon. Every man who has extensively practiced surgery is confronted with two things, namely, the high mortality rate that goes with radical Wertheim surgery, and the high percentage of post-operative recurrence of cancer of the uterine cervix. The great difficulty lies in seeing these cases early in their existence. Practically all of them come to us when the disease has advanced to a point when visual and digital examination of making a diagnosis is obvious. When this point has been reached 90 per cent have passed beyond the usefulness of curative measures of any kind. The slight percentage of recoveries without recurrence, whether the treatment be surgical or otherwise, is no argument in their use as a measure to be advocated indiscriminately. The hope of curing cancer of the cervix lies in early diagnosis and I am not entirely satisfied in my own mind as to whether surgery or radium and x-ray therapy offer the

best course to pursue. Personally, I have ceased to operate on cancer of the cervix where the disease has advanced to the point when the diagnosis is easily made. I believe that then radium offers a better palliative measure than does surgery or Percy's cautery. One cannot be too careful in the prognosis given these unfortunates. I am satisfied that the people as well as physicians are realizing that the hope of absolute cure in these cases lies in early diagnosis. It is a terrible condition of affairs for a patient to present herself with the entire lower segment of the uterus destroyed by cancer and to learn that this patient has been under treatment for months for ulcer of the womb. The saddest thing in this whole picture is the fact that these patients could have been saved but for the mistake in the diagnosis.

When any physician is in doubt as to the malignancy of a badly lacerated and eroded cervix he should have no hesitancy in calling for surgical and pathological consultation. It is just as important in borderline cervix conditions to have a competent pathologist at hand as it is in breast cases when breast neoplasms are about to be removed. Surgeons are extremely fortunate because, unlike the physician dealing with cancer of the stomach, we can, with the greatest of ease, secure a specimen of suspected tissue and immediately ascertain whether or not the trouble is suitable for plastic repair or a complete hysterectomy to be followed by high voltage x-ray therapy. The successful treatment of cancer, in my opinion, is not any one individual agent but a combination of early diagnosis, surgery, radium, x-ray and Percy's cautery, which, unquestionably, has a place in treatment in all forms of carcinoma. I believe that the internal use of colloidal gold is going to add considerably to our armamentarium in the treatment of cancer. The experience of Ochsner has proven it a benefit in the post-operative handling of these cases.

AUGUST JEROME LARTIGAU, M. D. (391 Sutter Street, San Francisco)—When all is said regarding the present treatment of cancer generally, the outstanding facts of experience remain that our present methods are on the whole inadequate and unsatisfactory. The keynote to more successful results lies, as has been repeatedly emphasized by Dr. Sherrick and many others, in the recognition of the disease in its earlier manifestations; and with this in mind the education of the laity and even the physician must be pushed to the point where only wilful self-neglect can prevent timely and proper treatment and a higher percentage of cures.

While there is an agreement as to the fundamental importance of this aspect of the problem, the merits and limitations of radio-therapy and operative treatment have unfortunately not yet been clearly determined. Many are now advocating the radium treatment of earlier operable cases of cervical carcinoma by radiation alone and the figures they advance in support of their claims cannot be disregarded, but, notwithstanding the brilliant achievements along these lines, it seems to me that for the present at least, radical operation followed by radiation or not, still appears to be the line of action which is most likely to yield the surest and best results. In advanced inoperable cases on the other hand, as well as in many of the borderline ones, radiation remains our most effective remedy, the palliative effects being nothing short of wonderful in many instances.

The question as to whether or not preoperative radiation should be routinely practiced is still a mooted one. Further experience will be necessary before any conclusions can be drawn regarding this point. In my own experience I have not observed any of the drawbacks mentioned by other writers; nevertheless, it is well to keep them in mind.

DOCTOR SHERRICK (closing)—There is just one point that I want to emphasize more strongly, i.e., the effect of x-ray and radium on the blood. As shown by Von Kiehm, even in castration doses there is a decided decrease of both white and red cells with a definite and significant drop in hemoglobin while the blood platelets increase. The blood picture is extremely slow to return to normal and convalescence is much slower. These factors we cannot ignore in dealing with massive doses of x-ray therapy and in our enthusiasm for radium in uterine carcinoma that is not far advanced and in prophylactic preoperative or in post-operative treatment.

ABOUT INFECTIOUS JAUNDICE IN UTAH

By JOSEPH H. PECK, M. D., Tooele, Utah

Tooele and Lincoln, towns of a common water supply, seem to suffer most severely, while Grantsville and Stockton, which each have a separate supply, are practically free from the disease.

The disease affects preferably children three to twelve years of age, no difference in the sexes. I have never seen it in a nursing baby and only three adult cases in five years.

I know of no treatment of any benefit except an earnest endeavor to keep up the water intake and watch for signs of an acidosis which may occur in the persistent cases.

DISCUSSION by George A. Cochran, Salt Lake City; W. W. Boardman, San Francisco; Donald J. Frick, Los Angeles; T. B. Beatty, Salt Lake City.

PROBABLY the most complete review of the infectious jaundice situation in our recent literature is a paper by Blumer, read at the San Francisco session of the American Medical Association, 1923. In this he tabulates the epidemics over the United States from the initial one, which occurred in Virginia in 1812, to and including 1922. The most striking thing about the incidence of the outbreaks is the great increase in number and distribution since the late war.

In his report he lists only one break in Utah, that at Kaysville, in 1915. I feel that this subject has been neglected in our state and that perhaps if it were drawn to our attention that it might be a means of getting more complete reports of the incidence in Utah and that a better means of control might be determined.

First as to the name: This condition is not the infectious jaundice of our textbooks. Most writers ignore it entirely and those who have done work on it are unanimous in stating that it is in no way related to Weil's disease. With exception of jaundice they have nothing in common.

Incidence: In the five years I have been living in Tooele, I have seen outbreaks, both in spring and fall, of each year, and Drs. Phipps and Davis tell me that they have had it to deal with for twenty-five years, at least in occasional outbreaks.

Tooele and Lincoln, towns of a common water supply, seem to suffer most severely, while Grantsville and Stockton, which each have a separate supply, are practically free from the disease. In 1923 almost every child in the Lincoln school, about twenty in number, was affected in a period of six weeks, and I will give below a detailed report of cases occurring in my own practice in Tooele during October and November of this year.

For those not familiar with Blumer's paper, I will give a brief description of the condition as we see it in Tooele County. A child shows loss of appetite, sometimes for a week before the onset of the severe illness, and if closely watched it will be noticed that its stools, though solid, are getting light in color and very foul. I have never seen fever at this stage. After this prodromal period vomiting commences and is usually very severe, many patients being unable to retain even water for twenty-four hours or so. This is accompanied by a fever of various degrees, some running as high as 105. After twenty-four to forty-eight hours of this the child

begins to show jaundice, some in conjunctiva only, more often, however, the discoloration is intense, the whole body being markedly yellow. This lasts rarely more than forty-eight hours when the child rapidly clears up and appetite and bowel movements return to normal, though the jaundice may last a week and the child refuse any food for an even longer period. On the other hand, light stools may give only clue to nature of condition.

The urine contains bile, never, however, showing albumin as in Weil's disease. Liver usually palpable and tender. The leucocytes are only moderately increased, 12-15000 being the maximum. No relapses or conjunctival hemorrhages as in Weil's disease, though a child may have a second attack. Itching is not as marked as in jaundice from other conditions. Bacteriologically, nothing has been discovered which sheds any light on the mode or cause of the infection.

I have fed urine soaked carrots to a pig and injected him intraperitoneally with blood from a severe case without upsetting his well-being in any way whatever. Weil's disease always being fatal to a pig and the causative spirillum found with ease in his blood.

Occurrence: The disease affects preferably children three to twelve years of age, no difference in the sexes. I have never seen it in a nursing baby and only three adult cases in five years. These in adults, however, occurred when no epidemics among the children were on hand, so probably could be classed as catarrhal jaundice, which is considered by Blumer as likely sporadic cases of the above condition.

Treatment: I know of no treatment of any benefit except an earnest endeavor to keep up the water intake and watch for signs of an acidosis which may occur in the persistent cases. I have not found it necessary to use glucose solution to combat it, but believe such a condition might arise in a debilitated baby.

Upon return of appetite children seem to relish zweibach and other starches and for several days are unable to handle the usual amount of milk without pain after ingestion.

The following tabulation of cases answers the question of its infectivity:

1. On September 28, Beth Porter, eight years old, took sick with vomiting, chalk stools followed by jaundice of four days' duration.

2. October 9, Marjory Orme, five years old, her playmate and neighbor, followed with same story.

3. October 11, Vivian Stephens, four years old, playmate of first two and cousin of Orme child, took sick.

4. October 13, June Staples, four years old, cousin of Orme child, who lived two blocks away and visited infected neighbors two or three times a week, took sick with same story.

5. October 20, Nathan Porter, three years old, cousin and occasional playmate of Beth Porter, living one-half mile away, had same course with exception of a diarrhea. No effort had been made to keep above children from playing with first case until jaundice was marked.

6. November 4, Willard Stephens, nine years

old, brother to case three, came down with same course.

7. November 13, Ned Stephens, three years old, took sick. No vomiting and only conjunctiva involved. Brother to case three.

8. November 15, Blanche Stephens, six years old, sister to case three, same course plus convulsions at onset.

By this time the mothers in the neighborhood agreed with me that the disease was contagious and kept their children at home, so our last new case was two weeks ago.

Several other cases occurred during this time, but could not be traced to this particular neighborhood. Three cases in the McBride family in Lincoln and one Shields baby were sick in October and several cases were reported to me by neighborhood gossip. These not occurring in my own families were not followed up.

Prognosis seems always good with no sequela, though deaths in women during pregnancy and very young children have been reported. The child, however, is most miserable for two weeks and I believe more school time is lost in our district from this than from tonsillitis or any other common condition.

In conclusion let me say portions of rural Utah, Tooele County at least, are suffering from an endemic disease causing vomiting and jaundice of ten days or two weeks' duration, markedly infectious to children of two to twelve years of age, for which no cause is known and no method of transmission is as yet discovered.

Tooele, Utah.

DISCUSSION

GEORGE A. COCHRAN, M. D. (Deseret Bank Building, Salt Lake City)—The cases of infectious jaundice observed during the past six months have numbered four. The infectious nature of the disorder has not been conclusive.

The ages range from twelve to eighteen years. The history of the cases are similar. The patient complains of malaise and fever with a dull, heavy ache in the epigastrium. The jaundice is progressive and becomes very intense. The temperature ranges between 100 and 102. Itching is slight. Food increases the discomfort. The urine is dark brown. Leucocytosis ranges between 12-14,000.

It requires three to four weeks for the disorder to run its course. I have not seen two cases in the same family but Dr. Peck's cases seem to establish that it is a disorder disseminated by contact.

W. W. BOARDMAN, M. D. (Union Square Building, San Francisco)—Doctor Peck's report calls attention to the confusion at present existing in connection with the various types of jaundice associated with gastro-intestinal disturbances and fever. A brief review of the literature will show a multiplicity of terms and confusion in their use.

It is generally recognized that epidemics of jaundice do occur, some of which are dependent upon infection by the spirocheta ictero-hemorrhagica. It is less generally recognized that in other epidemics, the spirocheta is not the etiological factor. In the majority of these latter epidemics, the active agent has not been discovered, although in some an organism of the typhoid-para-typhoid group has been found. Differentiation of these two groups of epidemic jaundice, on clinical grounds alone, is difficult or impossible and the only positive method must rest upon the demonstration or failure to demonstrate the spirocheta ictero-hemorrhagica. This fact explains some of the confusion in the literature, as several epidemics have been reported as due to the spirocheta ictero-hemorrhagica when there is no proof that such was the

case. It is therefore important to keep in mind that epidemic jaundice does occur in the absence of the spirocheta ictero-hemorrhagica, as pointed out by Peck and others.

Another source of confusion in this field is the commonly held conception of so-called catarrhal jaundice, as the result of obstruction of the ampulla of Vater. Jones, Minot and others have demonstrated the impossibility of differentiating catarrhal jaundice from epidemic jaundice of unknown etiology on either clinical or pathological grounds and it would therefore seem desirable to dispense with the term "catarrhal jaundice," substituting sporadic infectious jaundice in its stead. With this conception of catarrhal jaundice, the entire subject becomes clearer.

Following Jones and Minot, I should like to suggest the classification of all these types of jaundice as infectious, occurring either sporadically or in epidemics. The sporadic cases are the cases of so-called catarrhal jaundice, the etiology of which is as yet uncertain. The epidemic cases occur in two groups, the one due to the spirocheta ictero-hemorrhagica—the other due to, as yet, unknown agents.

Few cases of epidemic jaundice have been reported from the Pacific Coast—one by Tickell from Grass Valley in 1922, was accepted as dependent upon the spirocheta ictero-hemorrhagica, but without proof.

It seems probable that with a better understanding of this subject, more frequent epidemics will be recognized and it is to be hoped that with our improved methods of studying biliary tract infections, definite knowledge regarding the etiology of these conditions will be obtained.

DONALD JACKSON FRICK, M. D. (1136 West Sixth Street, Los Angeles)—Light cast on the field of infectious jaundice reveals a jumbled array from which Weil's Disease, through the work of Inado and Ido in 1915, has extricated itself. What remains, with its motley of terminology, is awaiting a careful untangling. The clinical differentiation of cases of infectious jaundice, with an effort to rule out Weil's Disease, is not as simple as one might gather from Doctor Peck's paper. Still with the definite results which are obtainable through guinea pig inoculation, Weil's Disease can be ruled out in any given case. Early in the disease the blood should be utilized for such tests, while after the ninth day the urine will contain the organisms in larger numbers than the blood.

Certainly Weil's syndrome should be included under any general heading of an acute infectious jaundice.

That a better understanding of this condition has differentiated it from the general class gives promise that gradually the causative agents will be sufficiently understood to make possible a complete classification under the heading, "Infectious Jaundice."

Doctor Peck has, in this study, ruled out spirocheta ictero-hemorrhagica as the etiological factor. His cases, fall, therefore, into the general class of unknown etiology.

Jones and Minot have made many investigations in this field, placing the sporadic case (formerly classified as catarrhal jaundice) definitely under the general classification.

Although it seems futile to haggle over classification when there is so little known of etiology, still there is nothing to be gained by retaining so archaic and meaningless a term as catarrhal jaundice.

Epidemics of infectious jaundice are of not uncommon occurrence, particularly in war times. It has been considered that in some of these large series of cases bacillus coli or members of the typhoid group have been the causative organisms.

The clinical similarity of these outbreaks is marked. The sporadic cases, though as a rule less stormy, present much the same general picture.

In a case of such persistently repeated outbreaks as Peck experiences in his section of Utah, one feels that a study of duodenal contents of these patients along bacteriological lines might yield fruitful returns.

Doctor Peck has here brought out interesting proofs in the seasonal incidence and geographical distribution of the epidemics in his section. In these, together with his observations of contact cases, he has laid a foundation for further valuable investigation.

In the widely diversified life of the average busy

practitioner there is so little time for other than purely clinical investigation that one must congratulate Doctor Peck on his careful study.

T. B. BEATTY (State Board of Health, Salt Lake City)—I wish to congratulate Doctor Peck on his careful study and timely paper on a subject which deserves more attention than it has received in this country, doubtless owing to the mild type of the disease, which is attended with an almost negligible mortality, and the further fact that the extent of its prevalence has not been recognized.

Dr. Peck's record of many cases extending over a long period in his locality undoubtedly could be duplicated in many places. Neither health authorities nor others interested in the study of the disease have had knowledge of the actual conditions as no provision has been made for systematic reports. It is my opinion that this situation should be remedied either through notification required by law as in the other communicable diseases, or voluntary reports by physicians to boards of health.

While the literature shows a curious diversity of opinion on nearly every phase of the subject, certain facts are obvious: the disease is severe enough to cause much interference with school attendance, suffering and other inconveniences, and it is communicable. These facts justify serious efforts on the part of the medical profession to clarify the existing state of confusion of ideas as to etiology, mode of transmission, prophylaxis, etc.

The only outbreak heretofore reported to the State Board of Health in Utah was that referred to in Kaysville which was reported by Dr. Sumner Gleason in 1915. About forty cases occurred and contacts were traced in nearly all of them similar to those reported by Dr. Peck.

The fallacy of the theory advanced by some writers that the disease always originates in and is spread through rats was definitely disproved in that outbreak as there were no rats in Kaysville.

I wish to assure the members of the society that the State Board of Health will render all the assistance in its power through its Laboratory and Bureau of Epidemiology in assisting them in their study of the disease and measures of prevention. I also hope that hereafter the board will be notified in all cases diagnosed as infectious jaundice.

Lesions of the Extremities Associated With Diabetes Mellitus—A series of fifty-two cases of diabetes mellitus with associated lesions of the extremities has been observed by Frederick A. Collier and Phil L. Marsh, Ann Arbor, Mich. (Journal A. M. A.). The cases were unselected and represent 8 per cent. of all cases of diabetes mellitus seen during this time. As an outstanding fact, all the patients in the entire group had mild diabetes of long standing. In no case had there been adequate treatment, and glycosuria had been uncontrolled throughout the course of the disease. In fact, the very mildness of the disease was responsible for its neglect by both patient and physician. It was only with the advent of visible complications that the patients came for treatment. All these patients presented lesions in the lower extremity, and none had significant lesions in the upper extremity. Of these patients, eight, all women, had ulcers that had not responded to local treatment. All of them had definite varicose veins, which were thought to be responsible for the ulcers. It is of interest to note that the knee-jerks were present in all but two of the patients. Under dietetic treatment, the ulcers healed promptly with a continuation of the same type of local treatment that had failed previous to the institution of the diet. In twenty-four cases, infection was the initial event. The portal of entry was through some break in the skin, as an abrasion from a shoe, the trimming of a corn, a crack in a callus, all trauma of a minor nature in an unwashed foot. From here the infection spread slowly or rapidly. There were twenty cases of gangrene; five of these cases were complicated by infection. The authors direct attention to the fact, however, that not all lesions of the extremities associated with diabetes mellitus are gangrene. The use of insulin aids treatment of the types with infections by preventing coma and abolishing glycosuria. The prognosis is still grave in the group in which there are both impaired circulation and infection.

THE X-RAY DIAGNOSIS OF DISEASES OF THE NASAL ACCESSORY SINUSES, WITH SPECIAL REFERENCE TO SPHENOID AND ETHMOID DISEASES

By ROBERT A. POWERS, M. D., *Palo Alto*

After many trials I became convinced that accurate ethmoid and sphenoid interpretation was more nearly possible with the stereo method and adopted the 107° angle plate with the addition of an upward tube shift, the patient being erect to bring out fluid levels.

Mapping of the ethmoid sinuses within definite bony landmarks is an uncertain method in many cases.

Steroscopes of the paranasal sinuses is a valuable method which should not be discontinued.

A combination of Granger's 107° angle with a 5-inch upward tube shift at 40-inch distance through a small dental cone, with a lateral and a Waters projection in addition gives the most useful information regarding the paranasal sinuses.

DISCUSSION by Robert R. Newell, San Francisco; Frederick H. Rodenbaugh, San Francisco; James B. Bullitt, San Jose; H. J. Ullmann, Santa Barbara.

THE need for a standard method of sinus radiography is great. The fact that so many methods are in use is proof of the inadequacy of any of them. While some difference of opinion occurs in the interpretation of maxillary and frontal sinus conditions most of the controversy centers about the sphenoidal and ethmoidal cells. As the condition of these cells is most difficult to diagnose clinically, it is important that the radiologist render accurate information. Frequently, too, errors in ethmoid interpretation are not uncovered due to their inaccessibility, which leads the radiologist into a routine which cannot fail in time to cast discredit upon the method and its value. A glance at the ethmoid capsule removed from the dried skull will show a complicated labyrinth of thin-walled cells which have completely honey-combed the bone. Indeed, sometimes even the wings of the sphenoid, the maxillae and the nasal bones are invaded as well as the middle turbinate bones. These multitudinous cells, unlike the mastoid, are completely surrounded by the bones of the face and skull. To correctly interpret bony thickening, erosion and exudate is difficult and, at times, impossible. A radiograph, made in any direction, will represent the superimposed shadows of from four to fifteen cells, in addition to those of the enveloping structures. Mastoid interpretation is easy in comparison as the cells can be uncovered without difficulty.

In an attempt to determine by which method or methods the most information could be obtained, I have studied the methods of Van Zwaluwenberg, Pfahler, Blaine, Grier, and Granger. Van Zwaluwenberg introduced the vertical stereoscopic shift which greatly aided symmetry. Pfahler projected the ethmoids and sphenoids vertically downward on an intra-oral or extra-oral plate. This method appears to have value in sphenoid interpretation, but has been found most confusing in ethmoid conditions as the ethmoid cells nearly always appear opaque. Blaine's method for standardizing sinus technique includes the 23° angle. The Waters position, a vertical extra-oral position advocated by Law, and a lateral view. He excludes stereoscopy and depends on 23° angle for the ethmoid shadows. Grier

omits the Waters position and the lateral, taking four postero-anterior plates, each one stereoscopic with the next—an excellent method, but incomplete, in being all in one direction, antero-posterior.

The exhaustive study of Granger has been found most useful. In brief, his method consists in using a perforated plate-changing tunnel with a hole for the nose, the head resting on the glabella and the alveolar process of the superior maxilla. One antero-posterior view is made on a 23° angle board. Another is made on a reversed 17° angle board. One lateral projection is made. Granger, by standardizing the position, holds that the ethmoid and sphenoid cells will fall within definite areas limited by bony landmarks and checked by comparing corresponding areas on the three different exposures. He also called attention to the curved line of the upper margin of the sphenoid in the 107° angle, mentioning that a thickening of this line meant hyperplasia, an absence, fluid, or polyps. While I have found these contentions to a certain extent true, certain difficulties arise in using the method unmodified. They are:

1. The exclusion of stereoscopy.
2. The normal variation of skull angles precludes absolute standardization of the 107° angle. In an examination of but a few specimens I have found a 15° variation, which is enough to alter the position of the curved line.
3. There is a normal variation in the thickness of the curved lines due to difference in degree of pneumatization of the sphenoid body.
4. A posterior ethmoid may and frequently does overlie the sphenoid and underlie the curved lines.
5. It is impossible to accurately map the ethmoid cells within prescribed boundaries due to differences in degree of pneumatization, the posterior ethmoids often invading the anterior ethmoid region and vice versa.
6. In the Granger 107° angle position, the ethmoids are obscured by the frontal, sphenoid and basilar portion of the occipital bone.
7. In the 23° angle plate they are obscured by the nasal bones, turbinate bones and the lower half of the antrum by the petrous portion of the temporal bone.

After many trials I became convinced that accurate ethmoid and sphenoid interpretation was more nearly possible with the stereo. method and adopted the 107° angle plate with the addition of an upward tube shift, the patient being erect to bring out fluid levels.

It was found that at normal distance, 22 inches, the second plate gave a projection similar to the 23° angle position and an excellent view of the ethmoid capsule, uncovered, but not of the sphenoids in all cases. At the suggestion of Drs. Chamberlain and Newell of Stanford University Hospital, the tube plate distance was increased to 40 inches, which brought out shadows at a distance from the plate. It was found, however, that at this distance a 2½ inch shift gave little displacement of the petrous portion of the temporal bone and the ethmoids were not sufficiently uncovered to be ideal. The shift was changed to 5 inches and the result was

found to be most gratifying, as one plate gave Granger's 107° angle position with the curved line and the other gave an excellent view of the ethmoid capsule. Viewed singly much was added to the ethmoid and sphenoid study and viewed together, it was found that the accommodation of the eyes gave a stereoscopic image quite as good as with the 2½ inch shift, but with a much more favorable uncovering of the pneumatic structures. All plates are made 40 inches in the erect position, using a small dental cone. The Bucky has not been found necessary. Indeed, the films appear clearer without it. A very definite idea of the ethmoid structure can be obtained both as to density and hyperplasia. The sphenoids are clearly brought out. A lateral view is added to determine the depth of the frontals and as a check on the location of ethmoid or sphenoid density. The Waters position is substituted for Granger's 25° angle position as the writer believes more information is obtained.

CONCLUSION

1. Mapping of the ethmoid sinuses within definite bony landmarks is an uncertain method in many cases.

2. Stereoscopy of the paranasal sinuses is a valuable method which should not be discontinued.

3. A combination of Granger's 107° angle with a 5-inch upward tube shift at 40-inch distance through a small dental cone, with a lateral and a Waters projection in addition, gives the most useful information regarding the paranasal sinuses.

The Palo Alto Hospital.

DISCUSSION

ROBERT R. NEWELL, M. D. (Stanford University Hospital, San Francisco)—Dr. Powers has gone ahead with the specialized x-ray study of the ethmoids and sphenoid. I, too, have adopted Van Zwaluwenberg's method of 40-inch distance and sagittal stereo. shift for the ethmoids. I would be very unwilling to give up the stereo., however much Granger may have taught us about the appearance of the sphenoid and ethmoids on single films. It seems to me worth while to take the films with the patient sitting, as does Powers, in order to show fluid as different from soft tissue filling the sinuses. I have found it worth while also to make one horizontal ray exposure with the patient lying on his side. Free fluid will gravitate to the dependent portion of the sinus and demonstration of this shifting proves that the observed density is in fact due to fluid and nothing else. I am using the Bucky diaphragm for routine sinus studies, believing that the contrast is thereby improved. I must agree with Dr. Powers that it is not essential, however. I continue to depend on the Waters position for the best x-ray evidence in regard to the maxillaries.

FREDERICK H. RODENBAUGH, M. D. (516 Sutter Street, San Francisco)—I have been greatly interested in observing Dr. Powers' demonstrations of sinus technique, and feel certain that he has done much to clarify the difficult phases of accessory sinus disease.

My practice has been to use Van Zwaluwenberg's technique in the examination of ethmoids and sphenoids, and it has been satisfactory. It is my impression that familiarity with the method will enable one to determine, with a fair degree of accuracy, the presence of ethmoid and sphenoid disease. In addition I have used a mouth film for a sagittal projection of sphenoids which has been helpful in determining the size of sphenoids, and their comparative densities. The diagnosis of ethmoid disease has not been successful with mouth films. As a routine I have not used the Bucky diaphragm, and have not felt the necessity for its use after comparisons.

Doctor Powers is to be congratulated on the technical

accuracy of his work and very interesting group of cases he has presented.

JAMES B. BULLITT, M. D. (Garden City Bank Bldg., San Jose)—The difficulties attending the study of paranasal sinuses are generally recognized by roentgenologists who have strongly felt the need of improved methods in the examination, especially of the sphenoidal and ethmoidal cells. Therefore the proposals of Granger were received with great interest, although his conclusions are yet to be confirmed. Powers disputes Granger's statement that with the 107 degree angle it is possible to make strikingly similar radiographs of very differently shaped heads. Powers in a few specimens finds a variation of as much as 15 degrees. As Granger's findings are primarily and largely based on the correctness of this proposition, it is to be hoped that further and accurate studies will soon appear dealing with this phase of the subject.

Powers' idea of using Granger's angle board position at a distance of forty inches and combining with it the making of stereoscopic plates with vertical instead of lateral shift, as proposed by Van Zwaluwenberg, appears most logical.

Doctor Powers' proposal appears to be a distinct advance toward the goal of a better exposition of the pathology of the sphenoidal and ethmoidal regions.

H. J. ULLMANN, M. D. (Santa Barbara Cottage Hospital, Santa Barbara)—I was much interested to hear that Dr. Powers had not been able to get essentially similar pictures with the Granger position. So far I have been fortunate in being able to do so, and it will be a blow to find that I cannot. Since using the Granger position and his recommended 107 degree angle, I have felt considerably happier in attempting to interpret films of the sphenoidal region, but the ethmoids still remain a great trial and stumbling block. Doctor Powers' method of combining the glabellar-maxillary position with a 40-inch distance and vertical stereo. shift appeals to me strongly and I am going to give it a trial.

DOCTOR POWERS (closing)—I hope that I have not given the impression that the method I am using is an easy solution of the ethmoid and sphenoid problem. It is simply an attempt to combine the best of many methods on four plates and has been found to be an improvement in my hands. Special cases will require more, such as the vertical intra-oral method in certain hyperplastic sphenoid cases.

Isthmospasm of the Fallopian Tube—Isthmospasm of the fallopian tube is described by W. T. Kennedy, New York (Journal A. M. A.), as being an obstruction between the meeting of the ovum and the spermatozoa and may be the only obstruction preventing the passage of a fertilized ovum from the tube into the uterus—a predisposing factor in ectopic gestation. Isthmospasm is one condition that will explain selective sterility. Attenuation of an isthmospasm would explain some conceptions. Isthmospasm exists in some women complaining of sterility or sterility and dysmenorrhea, and is frequently associated with antelexion. Isthmospasm is caused by the improper balance of the autonomic and sympathetic innervations, either the autonomic being in excess or the sympathetic being deficient. A tube, having an apparently normal ampulla and no evident abnormality of the isthmus, even though it obstructs the passage of carbon dioxide gas by insufflation, should not be removed at operation because we may render a patient permanently sterile who is now only temporarily so.

Raynaud's Disease Complicated With Gastric Ulcer—The case reported by Julius Friedenwald and William S. Love, Baltimore (Journal A. M. A.), presents a typical instance of Raynaud's disease complicated with gastric ulcer. While it is most difficult to demonstrate a definite relationship existing between the two affections as occurring in the same patient, it is extremely interesting to note, and it is quite possible to conceive, that both may have originated in a vascular spasm. That similar spastic manifestations of the blood vessels occur in the internal organs in Raynaud's disease is revealed in the well observed attacks of hemoglobinuria and of abdominal colic noted at times in this affection.

EXTRAPLEURAL THORACOPLASTY

SCOTT D. GLEETEN, M. D., *Monrovia*

This operation is generally applicable in patients where artificial pneumothorax is indicated and cannot be given. It may be done in any number of stages under local anesthesia.

It produces very little shock. I make a plea that it be more generally used.

DISCUSSION by *Ralph B. Scheier, San Francisco; Harold G. Trimble, Oakland; J. W. Robinson, Los Angeles.*

DISEASE of the chest presents to the clinician more problems in mechanics than that of any other part of the body and the recital of the obstacles met and overcome is one of the most interesting stories in medicine.

The evidences of disease within the chest have been carefully studied, particularly since Laennec; abscesses were recognized, the cavities of tuberculosis were diagnosed, bronchiectasis was known, but the problem of the treatment of these conditions by drainage and the approximation of the walls of the diseased areas within the rigid chest wall was one of great difficulty. Thoracoplasty, as a means of overcoming the rigidity of the chest wall, was first brought to the attention of the medical world by Carl Spengler in 1890. In 1905 Brauer and Friedrich adopted an operative plan similar to the Schede, which afforded excellent exposure of the ribs, but was attended by so much shock and such a high mortality rate that it fell into disrepute.

Wilms operation was much simpler and more easily done, was attended by much less shock and really gave impetus to surgery for the relief of subacute and chronic inflammatory intra-thoracic disease.

This operation consists of the removal of a section of the first seven or eight ribs through a para-vertebral incision followed in a few weeks by a section of the costal cartilages of the corresponding ribs. This allows underlying cavity or abscess walls to approximate, affords an opportunity for more or less lung rest and gives a vertical column of rib sections against which pressure can be made without injury to the underlying viscera. It does not, however, secure complete collapse either in the horizontal or the vertical plane.

Sauerbruch's operation done through a para-vertebral incision with removal of a section of the first to the eleventh ribs, including the angles, is the operation of choice. It is done in at least two stages under novocaine-adrenalin anesthesia. From 4-11 centimeters is resected from each rib, depending upon the ease of access, condition of the patient, etc.

I have been able to collect some recent reports of this operation, including H. Hauke, who says that as between artificial pneumothorax and thoracoplasty (Sauerbruch), thoracoplasty will be found the easier to perform. He believes the lung compression to be more uniform than in artificial pneumothorax. Gravesen uses Sauerbruch's method but he fortifies novocaine anesthesia with ether during the difficult parts of the operation.

Santy and Guilleminet also use a modified Sauerbruch operation in the treatment of bronchiectasis and quote Sauerbruch's report of thirty cases with but one death. Archibald follows Sauerbruch's plan, using a two-stage operation under novocaine and

nitrous oxide anesthesia. He says he used to think that artificial pneumothorax should be tried first but now believes that a certain percentage of cases do better if thoracoplasty is done in the beginning, such as where refills would be difficult to obtain. Hedblom reported a series of ten cases of unilateral, so-called, bronchiectasis, in which he used a many-stage operation with resection of 6-12 centimeters of as many ribs as he deemed necessary through a para-vertebral incision. After resection absolute alcohol was injected into the nerve trunks. The remaining sections of the corresponding ribs were later resected through an anterior incision. He used novocaine, fortified with nitrous oxid oxygen anesthesia. Thearle reports thirteen cases done by Sauerbruch's method with two cures and six markedly improved. He uses local anesthesia but does the work in one stage. Lambert and Miller review twenty cases treated by Sauerbruch's method. They are not clear as to the anesthetic used but append the results of several operators which I have taken the liberty of copying.

	No. of cases	Operative mortality pct.	Late mortality pct.	Total mortality pct.	Cured or greatly improved pct.
Sauerbruch	381	12	35
Gravesen	105	9	41
Stocklin	100	24	37
Bull	92	10	25	35	45
Archibald	15	14	8.5	22.5	42
Lambert and Miller.....	20	15	15	30	55

Watson reports four cases and advises that thoracoplasty be done in cases in which artificial pneumothorax cannot be given. He uses local anesthesia.

In my opinion there are four main types of subacute or chronic inflammatory intra-thoracic disease in which extra-pleural thoracoplasty may be indicated, and the indications for thoracoplasty are virtually the same as for artificial pneumothorax, namely, severe more or less unilateral cases of tuberculosis that are not doing well or that it appears will not do well under sanatorium or home care; severe more or less unilateral bronchiectasis or lung abscess cases that are not improved by postural drainage or vaccines; and the chronic unilateral post-influenzal cases resembling tuberculosis and requiring practically the same surgical treatment.

In the aforementioned types there is a great class of cases in which artificial pneumothorax cannot be given at all because of pleural adhesions, or in which the space is so small that no beneficial result can be expected from artificial pneumothorax, and cases receiving artificial pneumothorax who have lost their free spaces following an attack of pleuritis. In these cases thoracoplasty offers considerable hope. Neither the presence of air following a pneumothorax nor a small pleural exudate in the side to be operated upon is a contra-indication. Early unilateral renal tuberculosis, slight laryngeal involvement, or a bronchial fistula, need not interfere with the use of thoracoplasty. The contra-indications are other serious visceral diseases or complications of existing disease such as amyloid, etc. In general, the patients who are fairly well nourished and whose digestion is good, do best—notable gain in weight is rather

unusual following either artificial pneumothorax or thoracoplasty.

The patient who is about to be operated upon should be under the observation of the surgeon for some time and should be gotten into the best physical condition possible. The blood picture should be carefully studied and if an anemia is present appropriate remedies should be used. It should also be seen to that the elimination is good. If the patient is in the habit of clearing out cavities or bronchiectatic areas, this should be done before he is placed on the table. An hour before the time of the operation he should be given morphine sulphate grain, one-eighth, hyperdermatically, and another one-eighth grain of morphine may be given when the patient enters the operating room if it is thought necessary. He should lie on the least affected side with a folded pillow between the shoulder and the hip to separate the ribs. See that he lies comfortably and that the nurse is a good moral anesthetist. The 1 per cent novocaine adrenalin solution should be freshly prepared. We are in the habit of making a small wheal with a fine platinum needle as a point of entrance for the steel needles which are used for further infiltration. These needles are 22 gauge and four centimeters long, ten and twenty cc. Luer syringes are used. A wheal is first made three to four fingers' breadths from and parallel with the spinous processes extending from the twelfth to the fourth ribs. Through this the needles are thrust deeply in every direction until thorough infiltration has been made, paying particular attention to the points of exit of the intercostal nerves; about 400 cc. of novocaine is used in each stage. The incision is made through the wheal. More anesthetic may be used as the operation progresses. When the ribs are encountered the eleventh is quickly cleared of muscle and periosteum and resected close to the spine—the cut end of the rib is seized with a grasping forceps, drawn out as far as possible and a section 8 to 11 centimeters long is removed. After a rib has been resected the remainder of the sections can be removed much more quickly on account of the increased space in which to work.

It is quite important to avoid injuring the intercostal nerves and arteries but too much time need not be given to removing the periosteum. After the ribs from the eleventh to the sixth have been removed each intercostal nerve should be picked up and injected with a few drops of absolute alcohol. This prevents pain and makes further anesthetization much more easy if anterior section is contemplated. A long rubber twenty-four-hour drainage tube should be inserted and the wound closed in layers.

As a rule, since there is considerable sero-sanguinous drainage, a very large dressing should be applied and the patient should be asked to lie on the operated side as much as possible. Surprisingly little shock follows the operation but there may be rapid pulse and dyspnoea for two or three days. Occasionally a large amount of foamy, watery sputum is coughed up. No marked change may be noted in the patient's general condition following the first stage unless the disease be basal, but in three or four weeks the second stage may be under-

taken, using the same procedure. At this time it will be found necessary to have a retractor with a long, wide blade to elevate the scapula in order that the operator may work under it and some difficulty may be found in resecting the first rib on account of its position and shape. It is here that some operators use nitrous oxide and oxygen to supplement the novocaine.

The success of this operation depends largely upon two factors: First, a tractable patient, and second, the removal of as large a section of rib as possible. The test is said to be absence of palpable rib between the spinal column and scapula.

The improvement is rapid following the second stage and continues for a considerable time. It may be facilitated by various measures which tend to compress the operated side. The amount of sputum will be much lessened and in the tuberculous may become negative to tubercle bacilli. In any case, where amelioration of symptoms is not obtained by the two-stage operation, the remainder of the resected ribs may be removed through an anterior incision in as many stages as seems necessary, and complete collapse obtained in a horizontal plane.

The post-operative care differs considerably from that of a patient suffering from an acute surgical condition and is divided into two periods; that immediately following the operation and until the wound has healed, and that following the healing of the wound and until the patient is discharged. In the first period as little morphia as possible should be given since the action of the cilia of the epithelial cells should be preserved in order that mucus and pus may be carried up and expectorated. This may be materially assisted by a posture or position which the patient recognizes as giving him the greatest relief.

In the second post-operative period careful attention should be paid to the hygienic-dietetic treatment and the use of compression apparatus as before mentioned. A scoliosis is likely to occur with the convexity toward the operated side. It is rare that symptoms are produced by this condition but from the aesthetic point of view simple postural treatment may tend to prevent its becoming a source of worry to the patient.

The changes that occur in the collapsed lung are, of course, the approximation of cavity or abscess walls, collapse of air cells, a dilatation of the blood vessels and a passive congestion. The lymph flow is increased with better lymph drainage of the lung. The end result is a gross fibrosis.

The following case report is a typical one: Male, white, twenty-four years of age; family history negative to tuberculosis. He had the usual children's diseases. In 1914 left lobar pneumonia followed by empyema and a rib resection for drainage. He was in the service from April, 1918, to August, 1919, and was in the Walter Reed Hospital for acute bronchitis. In 1921, while attending the University of Wisconsin, he had lobar pneumonia again. About this time tubercle bacilli were found in his sputum and he returned to his home in Iowa. He later came to Monrovia and was in a sanatorium under treatment for some time. He suffered from very severe hemorrhages during March, 1922. His ex-

pectoration was heavy yellow and averaged about 100 cc. in twenty-four hours. His temperature gradually became normal but slight hemorrhages were frequent and weakness was marked. The patient seemed to be doomed to a life of invalidism with no prospect of being able to be about. Physical examination of the chest showed marked retraction of the whole left side, anteriorly and posteriorly, with a rib resection scar in the axillary line. There was a large cavity in the infra-clavicular region with bronchial breathing and there were numerous rales on both quiet breathing and cough. The apex beat was outside the nipple line in the fifth inter-space. The right side showed some pleural friction sounds and clicks but there were no evidences of activity. Pneumothorax was tried but no free space of any size could be found. On November 15, 1923, the first stage of a thoracoplasty was done and on May 15, 1924, the operation was completed.

His sputum now averages about 30 cc. in twenty-four hours; the cough is much less and he gets out and about with very little difficulty. He has worn a compression bandage for some time and has taken heliotherapy in his back-yard at home, both of which measures, I believe, are of great benefit.

137 N. Myrtle Street.

DISCUSSION

RALPH B. SCHEIER, M. D. (Flood Building, San Francisco)—The plea made by Doctor Gleeten for the more general use of extrapleural thoracoplasty is in accordance with the views expressed by the majority of physicians and surgeons who are interested in the diseases of the chest. Nowhere in the realm of medicine and surgery is the collaboration of the physician and surgeon so essential as in cases in which this operative procedure is indicated. Available statistics show the mortality following thoracoplasty varies from 15 per cent to 35 per cent. This high mortality will be materially reduced when greater care is exercised in the proper selection of cases suitable for operation. This can only be done by those especially qualified by years of experience in diseases of the lungs. Emphasis should be placed upon the statement of Doctor Gleeten that pneumothorax should be attempted in every case before resorting to the more heroic measure of thoracoplasty. The fact that artificial pneumothorax cannot be induced in 30 to 40 per cent of indicated cases on account of adhesions which obliterate the pleural space will contribute to a more universal application of thoracoplasty, as it is the only known procedure that offers any aid in certain cases of otherwise hopeless tuberculosis.

Case reports show that 50 per cent of those operated are either arrested or markedly benefited. The result following the operation depends not alone upon the skill of the surgeon but to a greater degree upon the skill of the diagnostician in selecting the type of case in which the operation is indicated, for no matter how skilfully the operation is performed, the final measure of success will vary with the diagnostic acumen exhibited by the specialist who advocates the operation. The choice of anaesthetic is of great importance. Ether is absolutely contraindicated on account of the liability of activating a latent tuberculous process in the opposite lung. Personally I have seen but few cases of tuberculosis requiring either artificial pneumothorax or thoracoplasty that did not show some involvement of the opposite side. I believe that Doctor Gleeten's method of local anaesthesia for resection of the lower ribs and the use of nitrous oxide and oxygen anaesthesia for the upper first and second ribs is the best plan of procedure.

While thoracoplasty is recognized as a wonderful advance measure in the treatment of tuberculosis and other lung affections, it still remains necessary for the patient to receive the benefit of proper medical treatment long after the healing of the wound.

HAROLD G. TRIMBLE, M. D. (Thayer Building, Oak-

land)—It is pertinent at this time to stimulate interest in a well-recognized surgical procedure in pulmonary tuberculosis. The question always arises, "When is the optimum time to advise an irrevocable procedure such as thoracoplasty?" Many times we wait too long, after the usual hygienic therapy, with bed rest, under satisfactory conditions, before advising lung collapse. Attempted pneumothorax is unsuccessful, and another long wait ensues, before thoracoplasty is seriously urged. Extension to the comparatively sound lung, in the meantime, results in an active bilateral lesion that does not warrant further active interference. On the other hand, the many comparatively extensive unilateral lesions that will respond to adequate hygienic care, do not warrant the too hasty use of an operative type of therapy.

There is a middle ground, however, that we, with increasing experience, will be able to tread more surely, and feel that in thoracoplasty we have made an invaluable addition to our armamentarium in the handling of a difficult type of unilateral lung lesion.

J. W. ROBINSON, M. D. (834 North Occidental Boulevard, Los Angeles)—There is no doubt that Doctor Gleeten has struck the keynote of treatment in certain classes. There has been too much pessimism and a tendency "to throw up the sponge" when a certain stage has been reached in certain of these cases. We owe it to the individual patient, and we owe it to the medical profession, to extend every aid possible to relieve symptoms and cure these cases. Trimble has well stated that there is a middle ground. There is no doubt but what the high mortality rate has discouraged many physicians from referring these cases to the surgeon. I believe this mortality rate can be materially reduced if cases are operated on earlier. It is not fair to an operation to wait until the patient is thoroughly exhausted, and organs, such as the heart and kidneys, show degenerative changes from long continued sepsis, before this operation is done. There is no doubt but what the cases should be carefully selected so that this operation, with its poor cosmetic effect, should not be done needlessly. The probabilities are, with more careful selection of cases, especially during earlier stages, and possibly through more refined technic, that the mortality rate will be materially reduced.

Doctor Scheier has well stated the necessity for co-operation between the physician and the surgeon. Probably all would benefit if there were more consultations between the two divisions in the scientific practice of medicine.

Dochez Scarlet Fever Antitoxin in Thirty-one Cases—R. H. Graham, Aurora, Ill. (Journal A. M. A.), has observed thirty-one cases treated with unconcentrated scarlet fever serum by the Dochez method. In the thirty-one patients treated, twenty-one developed serum disease. These reactions ranged in severity from slight urticarial eruptions to a generalized edema, and the temperature as high as 105 F. Six of the cases showed anaphylaxis in the first hour. Eighteen cases either occurred or recurred from the second to the seventh day. Nine patients had an elevation of temperature from 100 to 105 F. Serum disease occurred in twenty-one cases out of a possible thirty-one. The size of the dose apparently did not influence the reaction. Immunization was established in twenty-four cases, all of those treated the day of exposure. Serum injected the second day after exposure did not protect two patients out of three. Therapeutic injections gave little apparent relief. One advanced case showed no improvement with 40 c.c. of unconcentrated serum, and there was a serious serum disease.

Centric Puerperal Palsies—Centric puerperal palsies are of interest to the obstetrician, the neurologist and the internist. These palsies are usually hemiplegias, though commonly the face, arm and leg are unequally involved. Infrequently monoplegias occur. A primary partial aphasia may be the forerunner. James E. Talley and Dorothy L. Ashton, Philadelphia (Journal A. M. A.), analyze forty-two cases recorded in the literature.

ALLERGY AND ITS RELATION TO THE OTOLARYNGOLOGIST

By GEORGE PINESS, M. D. AND HYMAN MILLER, M. D.,
Los Angeles

Allergic diseases often limit their manifestations to the region of the ear, nose and throat.

Many of these manifestations are overlooked because of their true character remaining unrecognized.

This results in much unnecessary therapy, both topical and surgical, without relief to the patient or satisfaction to the physician.

Two hitherto undescribed types of allergic diseases of the nose and throat.

Importance of the nose and throat specialist interesting himself in proper methods of history notes and examination from the allergic viewpoint emphasized.

ACTIVE DISCUSSION—really a debate—by Hill Hastings, Los Angeles; Cullen F. Welty, San Francisco; Eugene R. Lewis, Los Angeles; Benjamin Katz, Los Angeles, and George Piness, Los Angeles.

THE close relationship between diseases of the nose and throat and allergy is no new story, nor is it our intention to again cover ground which has been the subject of innumerable investigations and discussions. Our purpose in again bringing the two subjects together is to attempt to present some new lines of thought with which we have been impressed in the last several years as we have observed the ever-widening field of conditions which are being so frequently brought into what was formerly thought to be the rather narrow province of allergy.

Allergy has been defined as a natural and often inherited state of human hyper-sensitiveness to proteins, more or less permanent in character, as opposed to anaphylaxis, which is an experimental condition of temporary character having much in common with it in symptomatology. Allergy, as commonly evidenced in humans, gives us the familiar pictures of hay-fever, asthma, eczema, urticaria and angio-neurotic edema, manifestations of cellular hyper-sensitiveness to proteins, be they derived from pollens, foods, animal danders or other less common sources. Emphasis is laid on the cellular nature of the hyper-sensitiveness in allergy, for on this fact rests the character of each of its manifestations. Thus it is that in hay-fever we have an essential sensitization of the mucous membranes involved, namely, those of the eyes and nose; in asthma, those of the lining of the bronchi; in angio-neurotic edema, of the sub-cutaneous tissues; in eczema, of the skin. However, it is rather a rarity than otherwise that a patient should show sensitization of but one of these localities and most commonly there is evidence of involvement either simultaneously or consecutively of several groups of cells. It is the simultaneous involvement in hyper-sensitivity of the skin that is the foundation of the extensive and successful work that has been done in the diagnosis of these conditions by means of the protein skin tests.

Perhaps the most easily recognized allergic manifestation which the nose and throat specialist meets is that of seasonal hay-fever. The patient's story of its seasonal character, the coryza, epiphora, itching of the eyes and nose and sneezing, make the diagnosis clear. Examination confirms it. The conjunctivae are red and swollen, the nasal mucous membrane is turgescient, edematous and exuding large amounts of aqueous material. So clear a pic-

ture does not require discussion. When, however, the same condition occurs as a perennial disease, or when, as we shall show, it occurs to a lesser degree, we find that the diagnosis is not only frequently overlooked, but unnecessary and sometimes harmful treatment, both topical and surgical, is indulged in in a vain attempt to give relief to the patient and satisfaction to the physician. After all, the duration of seasonal hay-fever is more or less temporary, and for the greater part of the year the patient enjoys good health. Moreover, its seasonal character makes it so easily recognized in many patients and the method of treatment by pre-seasonal immunization against pollens is so well known that it is becoming more and more rare to find patients being deprived of its benefits. On the other hand perennial types and types of minor degrees of severity are still frequently being treated with distressing lack of success. Being unrecognized as manifestations of allergy they are annoying in the persistency of their symptoms.

The picture of perennial hay-fever is similar to that of the seasonal type, yet with this distinction, that in the latter as a result of chronic turgescence we have more or less thickening of the mucous membranes involved. This results in interference with nasal breathing, and drainage of the sinuses, the presence of muco-purulent secretion, and even polypus formation. Sinusitis is present, but is the sinusitis the cause of the thickened mucous membrane, and polypi, or is it the result of their interference with proper drainage of the sinuses?

A case in point is that of a woman who had had repeated diagnoses of "sinusitis." Her antra had been repeatedly drained and polypi and tonsils had been removed without relief of symptoms which consisted of attacks of sneezing, epiphora, excessive nasal discharge and itching of the eyes, nose and throat, occurring only when indoors and at all times of the year. The patient revealed the fact that she disliked eggs, could wear no wool clothing and that cat odors would produce the above-mentioned train of symptoms. Study revealed the fact that the patient was sensitive to foods, cat hair and pollens. Elimination of the offending foods and and pollen, resulted in the patient being entirely relieved of her symptoms.

Similar stories are not infrequent. In 130 cases of perennial hay-fever which we have had under observation and found sensitive, operative procedures have been common in about 80 per cent. However, we do not intend to criticize the removal of polypi or the resection of septums when drainage is interfered with. These are common sense procedures when obstruction as the result of the chronic turgescence of the mucous membranes is marked. The point we do wish to make is that even when these things have been done the root of the evil often has not been removed, and the patient should be investigated from the allergic point of view. This means not only a thorough investigation into the patient's sensitiveness to pollens as in the seasonal type of hay-fever, but also a thorough investigation into the patient's sensitiveness to other sources of protein, this to include food proteins, the animal hairs and whatever other sources of protein the his-

tory of the patient may suggest, such as room dusts, and face powders. That all of these are prolific sources of protein sensitization in the production of perennial hay-fever a group of 136 patients shows. Of these only 58 or 23.4 per cent were due to pollens alone. Of the remaining 78 or 76 per cent, foods, animal hairs alone or in combination with each other or with pollens, were the cause. In this latter group we had examples of sensitization which required the exercise of much ingenuity to determine. Thus a woman presented herself with the complaint of constant sneezing, epiphora, rhinorrhea and itching of the eyes, nose and throat dating back a number of years. She had been tested to many of the proteins and pollens and pronounced to be non-sensitive, a diagnosis "vaso-motor rhinitis" being made. Local applications to the nose and throat gave no relief, septum resection and turbinectomy gave equally negative results. A careful history brought out the facts that the hay-fever was of a perennial type, not influenced by climate or altitude and that up to three years ago the patient had used a Java rice face powder, at which time she had changed to orris root powder. Our study was made with all the proteins at hand. Included were foods, pollens, epidermals, miscellaneous proteins and proteins extracted from the feathers of the patient's pillow and of the hair of her mattress. All proved negative with the exception of orris root which gave a skin reaction approximately 2.5 centimetres in diameter. The patient was told to change her face powder again to Java rice and no other treatment was advised. It is now six months since this was done and the patient has been completely relieved of her symptoms.

What has been said of perennial hay-fever applies in the same degree to another group of hitherto undescribed patients which we term "potential hay-fever" for want of a better name. These patients present a definite picture which is illustrated by the following typical case. A boy of 8 was said by his mother to persistently breathe through his mouth, use from six to a dozen handkerchiefs a day and to repeatedly catch cold in his head. An adeno-tonsillectomy had been done three years previously without relief and still no relief after a second adenoidectomy. One competent nose and throat specialist made the following observations: "Typical adenoid facies with mouth breathing, marked turgescence of the mucosa of the nose and throat and excessive lymphoid growth on the pillars." Similar pictures and stories have been observed frequently and in all age groups. All of these patients have been operated on, usually an adeno-tonsillectomy and frequently a sub-mucous resection and turbinectomy having been done. They may or may not have given a definite history of some easily recognizable allergic manifestation such as asthma, hives or eczema, yet on being examined by means of protein skin tests have, in a large proportion of cases, reacted positively to them. Interesting to note in the above case, after the patient had been found sensitive to certain perennial types of pollen and treatment by injection had been begun, the youngster for the first time had a mild attack of asthma, a constitutional reaction to his protein injection and confirmation of the fact that we were

here dealing with a definitely hyper-sensitive individual. In this group of cases the most important are those which in the history or physical examination show none of the usual manifestations of allergic disease.

C. H. Montgomery, in discussing the findings in such cases from the point of view of the otorhinolaryngologist, in a personal communication says: "In connection with the pharynx, a picture frequently seen in childhood is that where we have very marked redness of the pharynx with a hyperplasia of much of the lymph tissue of the pharynx which may be distributed both in the medial and lateral positions. This picture of redness and thickening with a swollen condition of many of the mucous glands situated here can frequently be seen without the presence of any pus being detected anywhere in the nose, sinuses or tonsils. There is also a considerable secretion of mucus and many of these cases have, in the past, unquestionably been associated with dietary or pollen conditions, but, until the recent work on allergy, the ideas concerning this condition were in extreme confusion and there was no way of arriving at any definite knowledge as to causation.

"In the epipharynx also the mucous membrane is seen frequently congested and weeping but without the presence of pus. In the nose again many of these children have swollen turbinates quite constantly, with difficulty in breathing and at times the mucous membrane may be of a dull red color and at other times pale and flabby in appearance. These are sometimes spoken of as intumescent. Such a condition naturally aggravates the obstruction produced by a deflected septum or a large bony overgrowth of the turbinates themselves. This same vaso-motor congestion extends at times up the eustachian tubes and invades the middle ears, giving here dusky drums which can not be differentiated from any tubal or middle ear congestion of a low grade bacterial type. This congested condition of the mucosa lining the nose, epipharynx and pharynx and extending frequently into the lower air tract produces a very favorable condition for the invasion of bacteria and I am quite sure that many a bacterial cold, so-called, is superimposed upon a congestion of the nose produced as a result of proteid irritation. In this connection a point of diagnosis is helpful, namely that where a patient comes complaining of frequent colds in the head absence of any chronic focus of infection in the head such as chronic pyorrhea, chronic tonsillitis, empyemata of the sinuses or a chronic suppuration of the middle ear, it is well to remember that this patient may primarily have a congestion of the upper air tract produced by protein irritation and followed in a day or two by a bacterial invasion. This complicates the picture from a diagnostic standpoint.

"It is my opinion that given a naso-pharynx free from a purulent infection—such as chronic pyorrhea, chronic sinusitis of any type or chronic tonsillitis—but where the patient complains of recurrent 'colds,' stuffiness in the nose, 'headaches' and so forth, that many a mistaken diagnosis has been made and septa have been straightened or turbinates crushed, amputated or removed without benefit to the patient."

Treatment with specific protein gives gratifying results. Here we have forty patients, mostly children, whom we have found sensitive to all types of protein, the sniffing, excessive discharge and mouth-breathing having disappeared along with the vacuous look of the adenoid facies and the frequent so-called colds in the head.

We have thus far three groups of cases frequently coming under the observation of the nose and throat specialist for relief of nasal symptoms; first, the frank seasonal hay-fever, second, the seasonal and perennial hay-fever with atypical symptoms and pathological picture suggestive of chronic sinusitis, which may or may not be accompanied by other allergic manifestations, and third, the sub-hay-fever group, the perennially stuffy-nosed mouth-breathers, subject to frequent colds in the head and potentially, hay-fever or asthma sufferers, but having as yet evidenced no frank manifestations of allergy. Many of these, and, in fact, the great majority of these patients come for first observation to the nose and throat specialist and it is to him we must look for the first recognition of their true character, making certain in each case before undertaking palliative or operative treatment that he has arrived at the correct etiology of the condition which is presented to him.

Much has been written in the past discussing the pros and cons of operative treatment on the nose and throat in bronchial asthma, an allergic condition of the bronchial mucous membrane, identical in all respects to that of the mucous membranes of the eyes and nose in hay-fever. We do not believe it to be necessary in this day of general recognition of the allergic character of bronchial asthma to discuss a question so evidently unrelated to nose and throat surgery. Suffice it to say that Kahn in a recent article on the analysis of ninety-four cases of bronchial asthma, that had been under his observation for a number of years, had the opportunity to notice the effects of nose and throat operations on thirty-three of them. In fifteen patients relief of nasal obstruction was obtained, in two of these atrophic rhinitis resulted as a serious sequel, in the other patients the operation was of no benefit. Kahn goes on to say further, "it would indeed be proof of the influence of nasal disease on asthma if surgical treatment could sometimes relieve the paroxysms, but in none of these cases has operation been so successful. In most cases the improvement that resulted, even as concerning the local condition, was only temporary and incomplete and in many cases the local condition for which the operation was performed recurred. Even in patients in whom there was definite relief of obstruction and in whom nasal breathing became free the asthma was not influenced. But in my opinion the nose and throat should be left alone in asthma except when the rhinological condition itself demands attention."

With the above we are in entire accord, our experience leading us to the same conclusions. In only one aspect of the subject do we look to the nose and throat specialist in this field, that is in those cases which are apparently bronchial asthmas of bacterial origin. Here we seek the aid of the nose and throat specialist in the removal of foci of infection.

Recognition of hitherto unrecognized forms of

allergy belongs as much in the province of the nose and throat specialist as in that of the man who confines all his attention to allergy. It is from such observations that the field of allergy is constantly being widened. Thus, to the well-known types as hay-fever, asthma, eczema and urticaria, have been added gastro-intestinal disturbances, bladder allergy and Meniere's syndrome by Duke. Recently, through the co-operation of the nose and throat specialist, we have been successful in adding a heretofore undescribed type of allergy producing a severe migraine headache.

A man of about 40 years of age came to us with the complaint that at frequent intervals for the last twenty or thirty years he had suffered from a very severe type of hemi-crania, limited to the left side, having found a free interval only while a student away from his home in California and living in Michigan. He had been to numerous nose and throat specialists, in addition to having undergone several very thorough general examinations without results. The patient was referred to us by Dr. C. H. Montgomery, who, on examination of the ear, nose and throat, found a picture which was to him highly suggestive of that found in many other cases of allergy with which he had experience. The patient was tested in the usual manner and found sensitive only to a few perennial grasses common to California. The skepticism of the patient induced us to perform an experiment on him to which he consented. The pollen of one of the grasses was blown about him into the air of the room in an attempt to see whether a typical attack of hemi-crania could be induced. Shortly after leaving the office the patient phoned that he was suffering from a typical attack. He was then given adrenalin hypodermically, with the result that the headache was almost entirely relieved. The patient, however, still remained skeptical and the experiment was repeated without his knowledge with exactly the same result. In addition to this case whose pollen etiology is rare, we have several cases, due to food sensitization which seems to be the more common etiological factor.

Our dependence on the nose and throat specialists in discovering such cases and in successfully relieving their annoying symptoms is quite evident.

What then should the nose and throat specialist look for in attempting to determine whether or not a case should go through the protein skin tests. Our experience leads us to place first emphasis on the careful history. Family history, which is of prime importance, should not be overlooked in that, as Adkinson has shown, 48 per cent of the sensitive cases give a positive family history of some allergic manifestation, be it asthma, hay-fever, eczema or hives. Personal history should include age of onset. This gives a clue as to the type of protein to which the individual is sensitive and our experience has shown that as the age of onset increases so does the frequency of sensitivity decrease. Whether the particular complaint of the patient is perennial or seasonal. A seasonal history is the clue to a sensitization due usually to pollens and occasionally to seasonal foods, while the perennial type may be due to one or a combination of groups of proteins. Place of onset and its relation to the continuity of the symptoms. Many patients are free in certain lo-

calities and not in others, be this locality ever so restricted—as for instance in the not infrequent cases where a patient finds relief away from a certain house or even room. Occupation is a factor since the etiology can often times be traced to this source. For example, hair-dressers sensitive to orris root, bakers sensitive to wheat, hostlers sensitive to horse-dander, etc. History of certain skin conditions, such as eczema, urticaria and angio-neurotic edema is important in that they are allergic conditions and bear definite relationship to the other allergies above mentioned.

A careful physical examination and in the case of the nose and throat specialist a careful examination of his particular field, for clues as to the actual character of the condition which the patient presents, and last, but not least, the protein skin tests.

SUMMARY AND CONCLUSIONS

Allergic diseases often limit their manifestations to the region of the ear, nose and throat.

Many of these manifestations are over-looked because of their true character remaining unrecognized.

This results in much unnecessary therapy, both topical and surgical, without relief to the patient or satisfaction to the physician.

Two hitherto undescribed types of allergic diseases of the nose and throat are described.

The importance of the nose and throat specialist interesting himself in the proper methods of history notes and examination from the allergic viewpoint are emphasized.

1136 W. Sixth Street.

DISCUSSION

HILL HASTINGS, M. D. (1136 West Sixth Street, Los Angeles)—I have had an opportunity to see the results in a number of patients that I have sent Doctor Piness. The results are good. In many cases there was an apparent cure; in others considerable improvement.

I am of the opinion that this work of Piness and Miller in treating hay fever and asthma patients, nearly all of which are of the allergic type, will stop a good deal of unnecessary nasal surgery. The rhinologist should be on the lookout for those patients.

Many of the so-called chronic catarrhal ethmoiditis cases, with or without polyps, should be studied by competent men doing this kind of work before any operative procedure is undertaken.

There is no question in my own mind that the pathological conditions found in the nose in such patients is secondary to the allergic hay-fever, rather than the cause of the hay-fever.

CULLEN F. WELTY, M. D. (210 Post Street, San Francisco)—In the study of disease of the ear, nose and throat, we have certain definite ways to begin an examination.

In a broad classification, we have to deal with: (a) malformation; (b) pathological conditions; (c) systemic manifestations in the nose and throat; (d) new growths.

With a more careful analysis of these particular groups, we can arrive at something definite along lines that are well recognized.

Malformations are usually of the septum that encroaches on some part of the turbinate or turbinates. Sometimes we have an "S" shaped deflection that encroaches on either side of the nose. Spines of the septum we include irrespective as to how they have been produced.

I wish to speak particularly on the high deflection of the septum, because I have seen so many high deflections of the septum that have not been corrected when the septum operation was performed. It seems to me that some surgeons do not carefully go into the subject

of "nasal contacts" and confine themselves to the proposition that the patient must have free respiration. So the septum operation is done and a contact is left high up that is responsible for a great many manifestations that the ear, nose and throat surgeons are quarreling about at the present time.

Now if we cannot agree as to a definite procedure and as to what we expect following a given operation, how can a physician not qualified as a specialist attempt to pass judgment in a given case? I do believe that contacts cause more trouble than any other condition alone. They may be responsible for headache, asthma, bronchitis, so-called hay-fever, as well as a persistent dropping in the nasopharynx, and eventually lead to real pathology in the formation of hypertrophies and sinus infection.

Regarding headache—I cannot say definitely that the individual case will be relieved by the removal of the contact. But bear in mind that nature did not intend to have it that way, and correct your malformation. In many instances the headache is gone forever.

Asthma in a patient with malformation—Now a malformation in the nose is not of itself a thing of any consequence, except when it does produce a contact and at such a time it requires the most careful consideration. This brings up another point as to when should a malformation be corrected. To make the proper examination for such a condition, your patient's nose must be well cocainized and an interval of fifteen minutes must elapse before the cocaine will have had its complete contracting power. At this time any contacts that may be found are acting in a detrimental way and should be corrected.

I have not cured so many cases of asthma, but I have benefited or made more comfortable every one that I have had to deal with. My reason as to why all these cases do not recover entirely is as follows:

Asthma is of necessity a chronic disease. It has existed for a long time prior to my seeing the patient and because of this long duration, real pathology has been produced in the lung. This lung pathology cannot be removed. The exciting cause whether from malformation or pathology in the nose or anywhere else in the body, is now cured (and I mean cured). The predisposing cause has been removed. So it naturally follows that for another attack of asthma, it takes a new exciting cause that may be found in most anything that will interfere with the mental attitude of the patient.

Bronchitis—A chronic hyperemia kept up by the secretions, mucous or purulent that drop into the lungs. I have seen many cases simulate tuberculosis, diagnosed tuberculosis, and treated for tuberculosis, only to be cured by the removal of the cause.

I believe such cases of asthma that have a recurrence by reason of food, drink or pollens, are so induced because of the chronic infection and pathological changes in the lungs that make them particularly susceptible to this particular stimulant. The same thing happens in so-called hay-fever. When I say that I am not familiar with hay-fever, you may be surprised. For I have not seen a case that I would call hay-fever from the descriptions that I have read from our teachers.

I have seen many patients who said they had hay-fever and that they suffer from this condition every season. I have seen patients with acute rhinitis from the poisonous effects of flowers and plants. In this whole group of cases I have found something that made that particular individual especially susceptible to this particular acute infection. However, it is not exactly an infection. It is an irritation or a poison, if you please, of the mucous membrane of the nose, entering by way of the contact, that part of the mucous membrane that is especially susceptible because of the contact. Accessory sinus disease, hypertrophies and polypi, will do the same.

So, in conclusion for hay-fever, I will say that I have never seen a case of hay-fever that did not have malformations, contacts, hypertrophies, accessory sinus disease or polypi.

Pathological Conditions—Before attempting to make a diagnosis every vestige of disease must be removed from the ear, nose and throat. I not only say removed, but I mean healed, well, free from discharge, and until such time, no one has the right to draw conclusions. This

applies to asthma, hay-fever, headache and various other clinical manifestations.

New Growths—Carcinoma, sarcoma, tuberculosis. They are so rare that we hardly need mention them, but they can produce asthma, hay-fever and headache in the same way that they are produced by contacts.

Systemic Disease—There is no doubt that organic disease will produce nasal obstruction by overfilling the turbinates with blood. There is no question that in some few given cases the mucous membrane of the nose becomes poisoned by food, flowers and plants.

In conclusion:

Allergy in its relation to otolaryngology depends upon certain definite conditions before you have the right to make a diagnosis.

First, that the patient's nose must be free from malformations and contacts.

Second, that the ear, nose and throat must be free from pathological lesions.

Third, that the ear, nose and throat must be free from new growths.

EUGENE R. LEWIS, M. D. (1920 Wilshire Boulevard, Los Angeles)—For over fifteen years I have been particularly interested in the phenomena which have been generally grouped under the two headings of "anaphylaxis" and "allergy." Unfortunately, my interest has always exceeded my ability to understand the essentials of the situation encountered in one of these patients. Certain findings seem to stand forth as characteristic in all patients, namely: (1) Sudden onset of acute irritation. (2) This condition always manifests itself on one of the body surfaces. (3) Absence of commensurate systemic effects indicative of toxicosis—fever, general malaise, prostration, anorexia, loss of weight, blood changes and the like. (4) Absence of local effects indicative of destructive agencies—surface or deep ulceration, abscess formation, indurative swelling, pus formation and the like. (5) Absence of after effects commonly following infections or traumatic processes—loss of normal tissues, fibrotic or cicatricial changes, adhesion formation and the like. (6) The termination of the acute irritation is typically as sudden and unexpected as its onset.

This briefly recounts certain outstanding characteristics of a typical non-infectious reaction. This may be complicated by pre-existent or by intercurrent infection, with or without purulence, clouding the picture very materially. I have seen a large number of patients who have been operated and reoperated upon with resulting unfortunate loss of functionally necessary nasal tissues, particularly turbinal and ethmoidal tissues, only to discover subsequently that their troubles were not abated as a result of the operations, but, on the contrary, were not infrequently increased. Careful differential diagnosis must precede any operative nasal procedures if we are to avoid such unfortunate results. *It would be as logical to amputate the skin sites of hives or of angioneurotic oedemas as it is to remove the nasal site of an allergic reaction.*

BENJAMIN KATZ, M. D. (520 West Seventh Street, Los Angeles)—I agree with the authors about the necessity of co-operation between the allergist and the rhinologist, because in neither field of these specialties is the symptom complex of hay-fever and asthma fully explained. In the fifteen years of my practice in nose and throat surgery, I have served many patients who were benefited by operative procedures in the nasal cavity. I admit that there have been instances in my experience, as in the experience of many other rhinologists, where operations have been of no avail. The authors mention instances of failure in patients treated surgically and state their successes by the allergic method of treatment in the same individuals. They do not, however, mention negative results of their methods, although to my knowledge such failures do occur. I wish to add that some recent researches in medicine show that in asthma, as well as in hay-fever, metabolic disturbance may be regarded as an etiological factor which may be successfully controlled by calcium therapy. Since neither of these methods can be recognized as a panacea in these affections, each patient should be treated according to the findings in the individual instance, by the co-operative efforts of all the physicians concerned.

DOCTOR PINESS (closing)—The statements made by Doctors Wely and Katz, relative to the results obtained in treating allergic conditions of the nose and throat by surgical procedures, have not been substantiated by other workers in the same field, namely Kahn, Lintz and ourselves, in that we have yet to see a single patient that has ever been cured by the procedures advocated by the discussers; neither can we subscribe to Katz's optimism relative to calcium therapy in asthma and hay-fever since, in a series of more than thirty-five cases, we have yet to see one patient benefited by this medication. However, we are willing to admit that cases of angioneurotic oedema and chronic urticaria have been given temporary relief by the administration of calcium chloride intravenously.

Our object in presenting this paper is merely to interest and obtain the co-operation of the otorhinolaryngologist in studying a group of patients who can be relieved of symptoms who have heretofore been unable to obtain relief by other measures.

Surgical Drainage in Infection of the Liver, Bile Ducts and Gallbladder—In all of these cases, before proceeding with the work on the gallbladder, Andrew S. Lobingier, Los Angeles (Journal A. M. A.), removes the appendix and any adhesions about the terminal ileum and hepatic flexure of the colon, and turns in the raw surface. The gallbladder is dissected free from the liver as in an ordinary cholecystectomy, but, instead of tying off the cystic duct, Lobingier clamps and cuts away the gallbladder 3 cm. from the choledochus. The cystic artery is located and tied separately. The funnel and the cystic and common ducts are explored for any stones that may be there. If the mucosa strips easily, a half-inch cuff is removed from the top of the funnel. A small, firm-walled rubber tube is now tied in place with two forty-day chromic catgut ligatures, with the end of the tube a centimeter proximal to the common duct. The rough edge of the gallbladder stump may be either turned in or covered with omentum. The denuded bed from which the gallbladder has been dissected is covered in by flaps in the usual way. The drainage is maintained for from twenty-five to thirty-five days, as repeated cultures may indicate. Care must be exercised to prevent dehydration from excessive drainage. As a precaution the tube is clamped at intervals, chiefly at night, if the drainage exceeds 8 or 10 ounces in twenty-four hours. As a further precaution against dehydration, an abundance of water is given by mouth and by hypodermoclysis. Lobingier says that this operation may be done rapidly and without danger of injury to the common duct. It is free from the objections that attend Kehr's drainage of the common hepatic duct, as there is no tube in the common duct to produce pressure-ulceration and subsequent stricture, a surgical tragedy always imminent after tubal drainage of this duct. It disposes of the tiresome controversy on cholecystostomy and cholecystectomy. It is a cholecystectomy, and accomplishes all and more than the usual cholecystostomy does in the drainage of the common and hepatic ducts. No infected gallbladder is left behind for future complications. Best of all, it drains and reduces the infection in the liver and pancreas, the *raison d'être* of practically 90 per cent. of gallbladder surgery.

Cavernous Sinus Thrombosis—The case by Sydney K. Beigler and Mark J. Bach, Madison, Wis. (Journal A. M. A.), gave very little evidence, either direct or presumptive, of an infectious etiology. It is quite apparent from the physical findings that the condition commenced with thrombosis of the right cavernous sinus. There was little if any evidence from the temperature, blood count, blood culture or history that this thrombosis was of infectious etiology. To the contrary, a severe diabetic condition, together with marked malnutrition and dehydration, pointed to a primary thrombosis of the sinus, with these factors as etiology. The progressive course of the involved areas indicated an extension of the thrombotic process to include first the left cavernous sinus and then probably through the inferior petrosal sinuses, the sigmoid and lateral sinuses.

OSTEOCHONDRITIS OF THE SECOND METATARSOPHALANGEAL JOINT (KOEHLER'S DISEASE)

By A. GOTTLIEB, M. D., *Los Angeles*

The etiology is still obscure, although chronic trauma of static incompetent feet is most likely to be the actual cause.

Adolescence and the female sex are predisposing factors and a constitutional weakness of the bone system may predispose to this disease as it does to the analogous conditions.

The diagnosis is simple in view of the characteristic changes occurring in the x-rays.

Correction of foot posture, partial immobilization of the affected joints and physical therapy will effect a symptomatic cure in about ten weeks. Operative interference is rarely indicated.

DISCUSSION by S. J. Hunkin, *San Francisco*; John C. Wilson, *Los Angeles*; George J. McChesney, *San Francisco*.

ADVOCATED by Lewin in preference to the misnomer "Koehler's Disease," metatarsophalangeal osteochondritis is a name applied to a condition of the second, infrequently the third, metatarsus and is characterized by definite changes in the metatarsal head, the distal half of the shaft and in the corresponding metatarsophalangeal joint. Previous to Koehler, Freiberg has observed and described the disease as an infraction of the metatarsal head; but only since Koehler's detailed presentation of five cases at the XI Roentgenological Congress of 1920 has it received consideration and been reported in literature. About ninety cases have been quoted by various writers up to February of 1924; to this number may be added the seven cases which came under my observation.

Etiology—In most instances the age of appearance has been the period of excessive growth of the epiphysis, 13 to 19 years. Although many cases have been observed in adults of various ages, adolescence seems to be a predisposing factor.

The most plausible of the disputed theories of development is the theory of chronic trauma which is based on the disproportion between the weight-bearing capacity of the second metatarsus and the exertion to which it is exposed. The theory is sustained by the anatomical fact that the second metatarsal head is projecting forward beyond the other heads and is receiving most of the superincumbent weight in walking. At the final act of each step, excessive burden is transmitted through the second metatarsal head, thus exposing it to direct pressure from above and to various insults from the unevenness of the ground below. The less frequent involvement of the third metatarsus can be explained on the same basis. The predominance of skin calluses under these heads, anterior foot swelling of soldiers, marching fracture of the second, rarely the third, metatarsal shaft, as well as traumatic periostitis of these shafts can all be attributed to the same cause, viz. constant weight-bearing pressure and chronic trauma. This theory is substantiated by the observation of most writers, including myself, that this affection is associated with pes transversoplanus, with flatfoot and frequently with halux valgus. Under these circumstances the metatarsal heads descend from their dorsal convex posi-

tion and receive the impact of the body weight with each step, whereby the second, the longest, head carries the greatest burden and suffers the most. Marching fractures or traumatic periostitis may result from stubbing this point of support when the shifting of weight is more or less acute; while osteochondritis, with the characteristic changes of Koehler, may develop when this static disturbance is constant.

As a contributing cause may serve the improperly fitting shoe with a high heel and a narrow box toe as worn by women who furnish over 75 per cent of the reported cases. But as an actual factor, the shoe can be blamed as little as direct trauma, which is denied in most cases. Both may only add insult to a pre-existing static incompetency of the feet.

Most writers suggest that a constitutional weakness of the osseous system serves as a predisposing element. It has, however, not been established of what nature this element is: Hormonic, toxic-infectious or diathetic, through which the body resistance is lowered and is manifested at a point of greatest strain.

Koehler, Baensch, Schreuder, Speed, Altschul and others sustain the theory of static disturbance and chronic trauma and contravene the opinion of Axhausen, who claims that the epiphyseal end arteries become obstructed by a mycotic embolism which may be of tuberculous or of mildly pyogenic nature. The weakly virulent infection of the embolus does not proceed to pus formation, but is overcome by the body resistance; only the mechanical influence of the arterial obstruction causes a deficiency of nutrition in the epiphysis and effects the development of the histopathological picture described below. In a latest contribution by Koenig and Rand, the theory of circulatory obstruction finds support; although they do not admit endarterial embolism, they derive to the same conclusions by presenting histological proof of occlusion of the periosteal blood vessels of the metaphysis.

Pathology—The gross lesion is seen in the radiograms which present definite characteristic shadows: 1. Changes in the proximal head of the third phalanx. 2. Considerable widening and irregularity of the joint space. 3. Flattening of the distal metatarsal head so that the circular outline is lost. The cap may be crushed in and give the appearance of the "egg shell" fracture of Skillern. 4. Calcareous deposits on the joint capsule. 5. Shortening and thickening of the distal end of the metatarsus, so that the normally dainty neck is obliterated. 6. The distal half of the metatarsal shaft is increased in circumference and the entire shaft may be shorter. 7. In the old cases the internal architecture of the head has reformed, although the shape of the head and shaft retain the characteristic stigmata of the condition.

Not all these cardinal changes may occur in every case, but a large number of them will be found in most cases.

The microscopic findings were obtained by Koehler, Axhausen, Fromme and others from operative specimens. In the epiphysis was found a wedge-shaped piece of necrosed bone which appeared grossly like a tuberculous sequestrum and presented microscopically an epiphyseal necrosis, or the spongy

portion contained necrotic foci and fibrous bone marrow which in places resembled granulation tissue. Young and old granulation tissue surrounded the necrotic bone separating it from the living spongy portion of the epiphysis. The granulation tissue was free of leucocytes, giant cells and bacteria. There was no trace of tuberculosis, rickets, lues or osteomyelitis; neither were there any findings of fracture. The cartilage was affected very little; it covered the necrotic tissue and the rest of the epiphysis. Some specimens presented villous hyperplasia of the sinovial membrane and lipping of the edges like in arthritis deformans. The distal half of the shaft had a thickening of the cortex and periostium which contained numerous blood vessels with thick walls and narrow lumina.

Baensch and Altschul explain these findings on the basis of chronic trauma: Through changes of static relations in pes planus and transversoplanus the second metatarsal head is exposed continually to greater pressure and is subject to contusions. This leads to pressure necrosis of the epiphysis which eventually breaks down in the direction of the shaft. While the spongiosa of the epiphysis undergoes necrosis and sequestration, the metaphysis of the bone is stimulated by the same, but lesser, pressure to proliferation of the periostium. New bone originates from the metaphyseal periostium; it penetrates into the epiphysis and spreads along the diaphysis. In course of time the proliferated bone rebuilds the epiphysis, giving it the characteristic shape, and alters the distal half of the metaphysis, causing it to thicken and widen. The joint cartilage and the cortex are preserved because they are capable of offering greater resistance than the delicate spongiosa.

SYMPTOMS

The patient complains of pain in the second metatarsophalangeal joint, or in the third if

this one happens to be affected. Both joints have not been found to be involved in the same case; neither has the condition appeared bilateral. The pain is especially felt on weight-bearing. Dorsal flexion of the toe is painful and motion is limited on account of muscle spasm. There is usually poor foot posture: Pronation, abduction of the forefoot, depression of the anterior and the longitudinal arches, deviation of the big toe and halux valgus. Swelling, palpable enlargement and sensitiveness on pressure are present in the region of the involved head and joint. The toe may be shorter and the flattened metatarsal head may lie proximal to the line drawn between the first and third heads. The leg muscles are not atrophied. The radiogram will reveal the characteristic changes enumerated under gross pathology.

DIAGNOSIS

A number of conditions of the forefoot may have to be eliminated. Morton's toe pertains to the fourth only and offers no abnormal shadows in the x-ray. Metatarsalgia is always bilateral, although it may be more pronounced in the left foot; persistent metatarsalgia in adolescence should be roentgenographed as likely to be associated with this condition. Traumatic periostitis of the metatarsal shaft and the anterior foot swelling of soldiers will give a history of prolonged marching, will present tenderness over more than one shaft and will reveal periosteal thickening in the x-ray. Fracture of the shaft or of the sesamoids will offer a corresponding history of accident and be shown in the x-ray. Low grade osteomyelitis and spina ventosa will be associated with a thickening of the bone in its entirety and be revealed in the x-ray. Any doubt in the diagnosis will be dispelled by the specific changes of Koehler presented in the radiogram.

PROGNOSIS

My personal observations lead me to believe

that the outcome of the acute cases is very favorable under conservative treatment. Even untreated cases have not resulted in any permanent disability or deformity, and have only been discovered during the examination for other complaints, mainly halux valgus.

TREATMENT

Weight-bearing pressure must be relieved by supporting the metatarsal shaft by means of a cup-shaped piece of felt to fill the area behind the affected joint. The pad may have to be extended to raise the entire transverse arch off the ground. A plantar splint, reaching to the second phalangeal joint and placed below the felt pad, will effect immobilization of the metatarsophalangeal joint and relieve it from superimposed weight. Complete immobilization I have not found necessary, but the patient should use the foot, even with the pad and splint, only within the limit of pain. A laced shoe with a semi-flexible shank should be provided. It should fit snug enough to make the foot follow its movements and should have a front sufficiently wide and long to permit spreading the toes and lengthening the forefoot in weight-bearing. The abduction and pronation of the foot are overcome by means of the valgus wedge inserted in the inner side of the heel and sole in order to tilt the foot and throw the body weight outward. The anterior heel, which has been recommended by some authors, is not to be advocated because it does not prevent the sagging of the metatarsal heads, but it favors the sinking of the longitudinal arch, besides making walking unpleasant and the shoe unsightly.

Besides the mechanical measures, the foot is subjected to physiotherapy: Incandescent light and heat, followed by quartz light exposure or by diathermy and concluded with mild massage and movements. As soon as pain subsides, the patient is instructed to perform exercises in order to strengthen the supinators and the intrinsic foot muscles. A valuable active-resistive exercise for the supinators is executed as follows: The patient places the outer border of the lower third of the leg on the opposite knee. She actively supinates the foot and resists this

action with the palm of the hand against the first metatarsal. For the intrinsic foot muscles, the patient places the bared feet in a basin of hot water and grasps with the toes small pieces of rubber tubing that float on the surface. This active resistive toe-gripping is more effective than picking up marbles.

CASE 1. G. McC., age 14. Girl. Since about 3 months she has pain in the left foot in the region of the second metatarso-phalangeal joint. Pain is worse when walking with shoes on and causes her to limp. Trauma strictly denied. Negative family and personal histories.

Examination—Mild swelling and marked tenderness over the distal head of the second metatarsal. The head is larger on palpation than the normal. On weight-bearing the anterior and longitudinal arches are flattened. Right foot is normal in the corresponding area. **X-ray**—Head is flattened and broadened; neck is obliterated; joint space is increased; a wedge-shaped piece of bone is driven toward the shaft which is increased in circumference.

CASE 2. G. G., Girl, age 14. Complains of pain and swelling in the left forefoot, especially over the third metatarsophalangeal joint. Duration four months with slow onset and without known cause. Past and family histories negative.

Examination—Slight swelling in the region of the third metatarsophalangeal joint which is tender and thickened on palpation. Plantar flexion of third toe is painful and motion is limited. Feet are everted and pronated and metatarsal arches depressed.

X-ray—Wider joint space, egg-shell fracture of the capitulum without callous formation and enlarged distal third of the shaft.

CASE 3. Mrs. A. L., age 40. Complains of pain in the right big toe and second metatarsophalangeal joint since about 3 years. Onset was slow; acute injury denied, but patient has to be a great deal on her feet.

Examination—Tender and semi-rigid halux valgus of moderate degree; enlarged and tender second metatarsophalangeal joint. Anterior and longitudinal arches are depressed on weight-bearing. Wearing high heels and pointed shoes.

X-ray—Characteristic Koehler's findings are present.

Treatment—All three cases were conservatively and were symptomatically cured in ten to twelve weeks.

CASES 4 and 5.—Both are women, ages 29 and 34, who come to have their painful "bunions" operated. Both complain of painful big toe joints and of metatarsalgia of many years' standing. There has always been more pain on standing in the area of the second, left, metatarsophalangeal joints. No acute injury known. Pa-

tients always wore high-heeled and pointed shoes. Past and family histories unimportant.

Examination—Marked halux valgus and tenderness under metatarsal arches, worse on the left side under the second toe joints. Outspoken pes transversoplanus and static flatfeet.

X-rays—Besides presenting typical changes of Koehler, both show restored trabeculation of the inner structure of the heads. Possibly a healed state of the disease.

Treatment—Halux valgus operation and post-operative treatment to restore the arches and regain muscle function.

Case 6. Mrs. L. T., age 38, has pain under the left metatarsal arch and marked tenderness in the region of second metatarsophalangeal joints since many years. Sustained no injury and was always in good general health.

Examination—Slight swelling and tenderness over the second metatarsus; depression of anterior and longitudinal arches on weight-bearing. Wearing stylish, ill-fitting shoes.

X-ray—Wider joint space; enlarged and flattened metatarsal head and somewhat thickened shaft. The diagnosis is doubtful since the appearance is not very characteristic.

CASE 7. Miss G., age 18, complains of pain and swelling for right big toe and of metatarsal pain in the right foot since about 3 years.

Examination—On inner surface of terminal phalanx is found a tumor mass which is tender and hard. Slight swelling over the second metatarsophalangeal joint and tenderness on pressure over the joint. Bilateral pes planus. X-ray reveals a bone tumor at terminal phalanx and finding of Koehler's disease.

Treatment—Removal of bone mass and conservative treatment for the metatarsal defect.

CONCLUSION

1. The name is chosen in conformity with the histopathological and radiographic findings.

2. The etiology is still obscure, although chronic trauma of static incompetent feet is most likely to be the actual cause. Adolescence and the female sex are predisposing factors and a constitutional weakness of the bone system may predispose to this disease as it does to the analogous conditions: Legg-Perthes, Osgood-Schlatter, Koehler's tarsal scaphoid and other epiphyseal diseases.

3. The diagnosis is simple in view of the characteristic changes occurring in the x-rays.

4. Correction of foot posture, partial immobilization of the affected joints and physical therapy will effect a symptomatic cure in about ten weeks. Operative interference is rarely indicated.

607 South Hill Street.

DISCUSSION

S. J. HUNKIN, M. D. (1155 Bush Street, San Francisco)—It is very opportune that Doctor Gottlieb has brought this new disease to our attention. It is unfortunate, perhaps, that two diseases even though somewhat similar in character should be called by the same name.

The disease which has been known as Kohler's disease for many years is of the foot scaphoid. This has been well known and readily recognized. This new disease is seen, as Gottlieb says, in chiefly the first and second metatarsals. Like the original disease, the etiology is unknown. Such pathological changes are seen in very many bones. It is akin, in my opinion, to what is known as Legge's or Perthes' disease in the femoral head and neck. We see corresponding diseases in the shoulder and in several of the carpals, especially in the scaphoid and semilunar. The character of the disease, as I have said earlier, is unknown, and up to the present we can only treat it tentatively; however, the treatment is a fairly satisfactory one.

The advantage of keeping it in mind is, of course,

to keep it distinct from tuberculosis and prevent radical operative procedure. These diseases have been known for many a long year, although without having definite names applied to them, in various parts of the body.

I am much pleased to read Gottlieb's paper, and personally I am obliged to have it brought so definitely and clearly to attention.

JOHN C. WILSON, M. D. (1136 West Sixth Street, Los Angeles)—Doctor Gottlieb is to be congratulated upon his exhaustive study and capable presentation of this subject. Fortunately, these cases recover with conservative treatment and this, in a way, limits our knowledge of the fundamental pathological process. It would seem that this condition is closely allied with the so-called Kohler's disease of the tarsal scaphoid and a condition commonly known as osteochondritis juvenilis deformans which involves the femoral head.

The study of the bacteriology of conditions of this type is just in its infancy. The oxygen content of bone is not definitely known. It is possible that bacteria grow in bone under anaerobic conditions, and that the failure to obtain cultures in cases that have been explored is due to the fact that attempts have not been made to cultivate these bacteria anaerobically.

GEORGE J. MCCHESENEY, M. D. (Fitzhugh Bldg., San Francisco)—Doctor Gottlieb is to be congratulated upon a rather unusual experience with this, as yet, little known condition. I am sure, however, that if orthopedists went over their case histories and x-rays of foot cases, they would find a fair number of unrecognized examples of this disease.

Two years ago I had a typical case in an overweight, adolescent girl. Removal of the second metatarsal head gave relief, but now I agree with the paper that conservative measures are usually preferable. In speculating upon the etiology, the frequency in the sex and age when narrow shoes are beginning to be worn is significant. The epiphyses are still ununited and vascular, and hence subject to injury. The occurrence of a congenitally long second metatarsal would render its head more vulnerable, just as a congenitally long first metatarsal, in my opinion, predisposes one to hallux valgus and bunions. These are only theories now, and time only will make them facts.

To the list of similar diseases elsewhere in the skeleton, as given in the paper and by the previous discussor, I would add Kummel's disease of the vertebral body. They all have change in bony texture and form associated with trauma and circulatory impairment, and absence of infection.

I would make one criticism of Gottlieb's outline of treatment where he recommends exercises for the foot muscles with the patient sitting. As in exercises for pes planus, the only ones really developing the foot muscles are those done with the weight of the body upon the feet, and sitting exercises are so easy for the foot muscles that flexibility is developed, perhaps, but not strength.

HEART PAIN

By T. HENSHAW KELLY, M. D., *San Francisco*

In order to intelligently prognosticate and treat heart pain, a knowledge of its probable mechanism and cause is a pre-requisite to success.

The heart muscle is not supplied with pain fibres and to have pain produced by the heart it becomes necessary to call into the equation the mechanism of referred pain production which was worked out chiefly by Henry Head.

In studying at autopsy about forty patients who died of angina, Mackenzie found, as many before him have done, that numbers of these patients had gross coronary sclerosis; others had marked constriction of the orifices of the coronaries, secondary to disease of the aorta, either syphilitic or atheromatous; the remainder had evidence of myocardial degeneration.

The attacks in primary heart pain are brought on by effort, by mental or emotional strain, by exposure to cold, sleeplessness, the taking of food and sometimes over-indulgence in coffee.

It is absolutely necessary that each patient's activities be restricted to a degree fully commensurate with his particular limitation of effort, but, undoubtedly, the wind must be tempered to the shorn lamb and patients with mild degrees of disability must not be chained to beds or chairs by thoughtless doctorial dicta based upon personal routines developed by physicians in order to conserve their valuable time and thought.

DISCUSSION by Harry Spiro, San Francisco; Roland Cummings, Los Angeles; Frank B. Reardan, Sacramento; J. Edward Harbinson, Woodland.

HEART pain is a symptom which causes a great amount of fear and apprehension to patients and is often the cause of great uncertainty on the part of physicians in so far as the prognosis in the individual is concerned. It occurs in both young and old, more particularly the latter, and may vary in intensity from a slight sensation of precordial uneasiness during effort to an agonizing pain involving the precordial area, the inner aspect of the left arm and little finger of the left hand, sometimes a similar area of the right arm and occasionally the neck or the ramus of the lower jaw. The severe attacks are often accompanied by a sense of constriction about the thorax and a fear of impending death and the patient may at the end of an attack pass large amounts of pale urine. It is these severe attacks to which the name angina pectoris was given and which were first systematically described by Heberden in 1768.

No disease produces more fear in the hearts of its victims and the numerous instances of death during an attack will justify these apprehensions, so that it becomes necessary for the physician to bring all of his skill and powers of observation to bear on each patient, that he may be assured of as long and as comfortable a life as may be his due. In order to intelligently prognosticate and treat heart pain, a knowledge of its probable mechanism and cause is a pre-requisite to success.

The cause of the pain is known to be dissimilar to that pain produced by injury to the skin or skeletal structures, for the heart is not supplied with pain fibres of the same type. There have been many theories advanced, but two have been held longer than others, the first of which, advanced by Lauder Brunton and others, suggests that the attack is due to over-distension of the ventricles, thus resulting in pain similar to that occurring when any of the other hollow viscera are over-distended:

Many patients, however, suffer from angina without showing any evidence of cardiac dilatation; many patients who have acute dilation of the heart have no pain and healthy hearts can be quite markedly distended by effort without pain until the effort has been continued long enough to approach a stage of cardiac muscle exhaustion.

The other theory, first suggested by Allan Burns in 1809, and today strongly championed and justified by Mackenzie, is that which says that heart pain is due to a heart muscle which is forced to contract in an insufficient blood supply. This insufficient blood supply may be the result of coronary disease or due to a diseased heart muscle which becomes exhausted in an attempt to maintain a sufficient peripheral circulation. The present basis for belief in this origin of heart pain may be briefly discussed.

The heart muscle is not supplied with pain fibers and to have pain produced by the heart it becomes necessary to call into the equation the mechanism of referred pain production which was worked out chiefly by Henry Head. He showed that the viscera do not possess tactile and pain sensibility, but are supplied by the vegetative nervous system with fibres which enter dorsal spinal roots belonging to definite cord segments. Within the cord these fibers are related to fibres, both motor and sensory, which go to the periphery and carry impulses regulating muscle tone, cutaneous sensibility and other less understood functions. These nervous system activities are carried on without any of the stimuli reaching the consciousness.

However when inflammation or disease of a viscus occurs, the number and intensity of these afferent stimuli from the organ to its cord segments increases and the peripheral motor and sensory elements in the segments which are in relation with the sympathetic supply to the diseased organ are so stimulated that muscular rigidity in skeletal muscles occurs and pain is felt in the corresponding peripheral skeletal areas supplied by their cord segments, often accompanied by hyperalgesia of the skin. The pain and hyperalgesia are always distributed according to segmental supply and not according to the distribution of peripheral sensory nerves. This is similar to the distribution of the eruption in herpes zoster.

Mackenzie, with this work as a basis, found that the areas over which pain is felt and over which hyperalgesia occurs following heart pain, correspond to the segmental skin areas supplied from the first, second, third and fourth dorsal segments of the cord. More rarely the pain may be felt higher in the neck or lower in the epigastric region, showing spilling over of stimuli into adjacent cord segments, the heart being supplied by sympathetic fibres arising from the first, second, third and fourth dorsal segments also. Thus the distribution of pain in angina pectoris is that of referred pain. The motor effects are not so clear to observation, but Mackenzie feels that the sense of constriction complained of by many patients is due to spasm of the intercostal muscles.

In studying at autopsy about forty patients who died of angina, he found, as many before him have done, that numbers of these patients had gross coronary sclerosis; others had marked constriction of

the orifices of the coronaries, secondary to disease of the aorta, either syphilitic or atheromatous; the remainder had evidence of myocardial degeneration. This fact inclines him to the belief that the pain arising from heart disease is due to a muscle which is contracting without a sufficient blood supply, or a diseased muscle which is exhausted attempting to maintain sufficient circulation. In both cases the effect on the muscle is similar to that of exhaustion and pain arising in the muscles of the legs in intermittent claudication and in normal muscles which are made to contract while rendered experimentally ischemic.

The abnormal impulses resulting from the contraction of the exhausted heart muscle then pass in to the cord over the sympathetic fibres from the heart, entering the first to fourth dorsal segments and resulting in referred pain felt in the skeletal areas supplied by these segments, and the amount of cardiac damage necessary to produce pain depends, therefore, upon the irritability of the cord in the individual patient.

Mackenzie feels that there is a group of women under fifty, and often at or near the menopause, whose nervous systems are so hypersensitive that stimuli arising in an almost normal heart during excitement or effort will result in heart pain and it is known that after continued attacks of angina pectoris the nervous system sometimes becomes so irritable that the pain is constant and may be aggravated by the touch of the bedclothes in the hyperalgesic areas. This state is known as the status anginosus. The group of women referred to above he designates as patients with secondary angina, distinguishing them from patients with definite cardiac disease and pain—the group with primary angina pectoris.

If we accept as fact that heart pain is produced by a heart muscle which is exhausted in an attempt to maintain circulation, we see that in heart pain we have the cause of symptoms in the heart muscle itself while in heart failure the symptoms are respiratory and are due to an insufficient cardiac output. We are in a position also to predict the causes of attacks of heart pain.

The attacks in primary heart pain are brought on by effort, by mental or emotional strain, by exposure to cold, sleeplessness, the taking of food and sometimes over-indulgence in coffee. The attack does not always immediately succeed the cause but may come on some minutes or hours later. This must be remembered.

In the second group the causation of attacks is not so clear, but they often occur from causes similar to those in the first group, but occur as a result of less cardiac disease and a more irritable nervous system. In these patients there is usually a sense of exhaustion present between attacks and the attack is often accompanied by marked exaggeration of the symptoms with widespread pain and persisting hyperalgesia.

The diagnosis of heart pain must be made in order that treatment may be instituted and a damaged heart protected from further strain. The typical attack of angina does not present much difficulty, the agonizing pain, the sense of thoracic constriction, the feeling of impending death all go

to make a definite picture. It is those patients who have epigastric pain, or pain appearing in the neck or arm that present the difficulty. It is necessary to remember that the pain is usually brought on by some factor which puts strain upon the heart and the relief by the nitrites is often of aid in clinching the diagnosis. It is needless to say that a careful examination must be made to rule out all other possible causes of pain, recalling that no other visceral lesions except rupture of the lung and some mediastinal disease produce arm pain. These two latter lesions may do so, but rarely, and others signs are present to point to the nature of the trouble.

It is also necessary to be on the alert to recognize pain not precordial in location as pain originating in the heart. It occasionally happens that the pain is referred down the cord and appears in the epigastrium, as in one patient, a man of 50, who for months had had shortness of breath and epigastric pain on effort, the pain accompanying an enlarged, passively congested liver. The pain was, for a long time, interpreted as liver pain, until one day, after getting into bed he had a similar attack of pain in the epigastrium, accompanied by pain down the left arm. His succeeding attacks were all characterized by pain in both locations.

The prognosis of heart pain of primary type is grave, but not without hope of some years of life in many instances. It is necessarily uncertain, because the exact extent of cardiac disease underlying it cannot be definitely ascertained, and the intensity of the pain is notoriously a poor index of the severity of the disease. Broadly speaking, the cardiac changes underlying the symptoms are, in most instances, those of advancing years and as might be expected, the greatest number of deaths from angina occurred between 50 and 60 years of age in a series reported by Osler and between 60 and 65 years in Mackenzie's series. The majority of patients die within five years of the onset of their symptoms, according to Mackenzie's experience.

This being true, the best method at hand of estimating the probable outcome of recurring attacks of heart pain depends upon the degree of limitation of effort and the rate at which this limitation increases. It is usually justifiable to assume that a patient who can perform considerable effort before symptoms appear and who has had this symptom on effort for some period of time is not in immediate danger. Contrariwise, a patient who is stopped by pain upon slight effort and whose disability has rapidly increased in extent is liable to an early death. Herein lies our most reliable information upon which to base a prognosis, but it likewise is not infallible.

Luetic disease of the heart may, in some instances, be ameliorated by treatment, but in others treatment is without avail and in these patients the prognosis must often be based upon the successful or unsuccessful outcome of treatment.

In the group of secondary angina in women, the prognosis as to life and improvement is more favorable after all possible causes of the general ill health have been found and eliminated, but constitutionally many of these patients are unfavorable subjects for complete recovery. The danger in them is not so

important, however, the discomfort holding first place.

The treatment of the attack is almost universally understood. The use of whiskey, the nitrites or morphine, depending upon the severity of the particular attack, is almost household knowledge. The patient puts himself at rest in most instances, but it is our duty to insist upon it if he has not done so. In the severe attacks a quarter of a grain of morphine sulphate may be used hypodermatically every fifteen or twenty minutes until relief is obtained and occasionally it may be necessary to use chloroform by inhalation.

Knowing that it is cardiac effort which produces the attack, it is the duty of the physician to arrange the patient's life so that he can lead an endurable existence with a minimum of effort and it is in this province of therapeutics that so much injustice is done.

First, it becomes necessary for us to do all in our power to allay the great amount of fear usually suffered by these patients and this is best done by taking enough of our more or less valuable time to explain to the patient, in language that he can understand, the nature of his trouble, stressing the hopeful factors and minimizing the hopeless ones. The latter can be discussed with a responsible member of the patient's family. Having done this, the rationale of his treatment can be explained to him and he will pursue his daily routine minus the terrible burden of fear frequently put upon a patient by the curt and courageous physician who more or less theatrically states simply that he has angina pectoris, puts a heavy band of restrictions about him and leaves him to investigate among his friends and acquaintances, the number of their friends and acquaintances who have died suddenly from the same disease.

Thus the patient is taught that hill-climbing, running and out-door sports are not alone added burdens upon his heart, but that worry, anger, fear, intense mental activity and over-eating and drinking also bring their share of strain upon it. He should be encouraged and perhaps aided to adjust business and domestic worries if these exist.

He should be taught further that the slightest sensation of heart pain is the best indication of the limitation of effort of his heart, and that this limit should never be exceeded. If an exceptionally great effort induced the first attack and the patient is seen then, a period of bed may materially reduce his limitation of effort.

A proper amount of rest must be enjoined upon the patient and if sleeplessness interferes it must be controlled by bromide or some efficient hypnotic. Excessively nervous patients may be given sufficient bromide or other sedative during their waking hours. A rest in the middle of the day or after each meal may be required in certain patients.

The sleeping rooms must be kept warm for the patient's dressing and undressing, to guard against exposure to cold. He should be warned against walking in cold winds or doing his usual level walking against a strong wind which materially adds to his effort.

The diet should be regulated so that no great

weight is gained as a result of the enjoined rest and it is sometimes advantageous to remove some weight by suitable measures. The food should be easily digestible and the bowels should be well regulated.

A thorough search should be made for any possible disease which might be contributing to the cardiac damage. Lues, focal infections in the tonsils, teeth, sinuses and other parts of the body should be searched for and removed as far as possible. Gastro-intestinal disease must be controlled so as to eliminate irritating and disturbing symptoms and all factors which tend to disturb the patient should receive attention.

In the group of secondary anginas all disease processes should be sought for and removed and the general health looked after very carefully. Menopause symptoms should be eliminated by all possible methods and sedatives should be used whenever necessary to hold down a hyper-sensitive nervous system. Reassurance should be offered these patients in considerable quantity.

In the severest cases where bed rest and other measures have not sufficed to prevent frequent and severe attacks it may be decided to try excision of the cervical sympathetic, as advocated by Jonnesco and as has been done by Coffey and Brown and others. This surgical measure provides relief of pain, but of course does not alter the ultimate end to any great degree.

It is absolutely necessary that each patient's activities be restricted to a degree fully commensurate with his particular limitation of effort but, undoubtedly, the wind must be tempered to the shorn lamb, and patients with mild degrees of disability must not be chained to beds or chairs by thoughtless doctorial dicta based upon personal routines developed by physicians in order to conserve their valuable time and thought. These patients have their lives to live until their hearts finally give up the struggle and it is our duty to give each patient the time and study necessary to add to the latter chapters of his life as much pleasure and enjoyment as his damaged heart is able to carry under our sympathetically careful guidance.

240 Stockton Street.

DISCUSSION

HARRY SPIRO, M. D. (Flood Bldg., San Francisco)—Doctor Kelly has not attempted to state all the facts and theories involved in this intense subject of Heart Pain—time forbade him. He, no doubt, could talk all night and not exhaust the subject.

This question of cardiac fatigue as a cause of cardiac pain gives plenty of room for argument. The heart is an extraordinary organ. It is almost impossible to fatigue it in the sense of skeletal muscle fatigue. The more you stimulate the heart the speedier it contracts, and the weaker it gets as a rule the faster it works. One of the principal signs of heart fatigue is rapidity of action. If pain were a sign of heart fatigue we would have pain oftener. Then, plainly, something else is needed besides ordinary fatigue as a cause of cardiac pain. "A deficient blood supply in the face of sudden demand," is a very frequent cause. The healthy heart with healthy vascular supply always has enough blood to meet its requirements, this supply being automatically regulated to the demand. But a nearly healthy heart with a defect in its vascular system, is not ready for an unexpected demand, as the heart continues to contract, sufficient blood supply or not, but it cries in anguish; it

answers the unfair demand by calling forth pain. This, as a cause of cardiac pain, has been shown to be probably correct by hundreds of autopsies.

I am in particular interested in aortitis as a cause of cardiac pain, or rather as a cause of angina pectoris. Patient after patient complains of pain exactly as described by Doctor Kelly. Careful physical examination reveals nothing unusual. Frequently an x-ray picture will show the heart normal in size and shape and one is almost tempted to say that the patient has false angina, particularly so if he has a normal blood pressure. But if you would carefully measure the aorta you would find that either the ascending or descending aorta has increased in width.

Or, if radiograms are taken after first placing the patient in various angles, you may see a slight bulge at the root of the aorta. You then are in a position to make an exact diagnosis of angina pectoris of aortic origin.

I beg of you not to forget that these are the types with normal blood pressure when you are examining them, but take the blood pressure during an attack of pain and you may see a rise of 100 points in the systolic, and even 50 or 60 points in the diastolic. Here is sufficient cause for agonizing pain—a sick aorta suddenly subjected to great pressure. This type, I believe, is the only type favorable for surgical interference, and frequently the only type which will yield to any treatment.

ROLAND CUMMINGS, M. D. (Pacific Mutual Bldg., Los Angeles)—From my observation I believe Sir Clifford Albutt's contention is well taken that the pain in angina pectoris is not precordial but post-sternal. As the impulses spill over into other cord segments, it may be most any place, but usually when patients are asked to point to the area of pain they will indicate an area over and just to the left of the sternum. This is of not great consequence, however, other than the endeavor to state things correctly tends to keep one from being so fuzzy-minded.

The discussions as to the cause of the pain are interesting, but all are still unproven. It occurs to me that in one case the cause might be the distention of the presigmoid portion of the aorta, and in another case due to a cardiac ischemia from coronary sclerosis.

I believe Doctor Kelly's consideration of the group of patients having anginal pain at about the time of menopause very important. May I add to this the great group which one might class under the head of the fatigue states. These patients have pain typically located, but much milder and more persistent than in primary angina pectoris. These pains do not come on suddenly in the form of attacks, but will develop insidiously following exercise or excitement. I have repeatedly seen patients with a deep aching in and slightly to the left of the mid-sternal region, radiating up to the left side of the neck and down the left arm, in whom their was no sign of sclerotic changes, neither history suggesting heart disease. The blood pressure may be lower than normal. These pains may persist for hours or even days.

I have a patient now whose blood pressure when she has this trouble will be as low as 85. Adrenalin hypodermically always helps her, and at times gives complete relief.

These pains are not due to organic changes of the heart or aorta, but must in some way be due to vascular fluctuations coming from an unstable nerve supply.

FRANK B. REARDAN, M. D. (Physicians' Building, Sacramento)—From the patient's point of view heart pain is an extremely important affair. His attitude toward it is not only, what is it? why is it? but what can be done for it and its cure? Clinically, the symptom is not common to any one pathological condition. As Dr. Kelly has reminded us, this is extremely important as regards prognosis and treatment. Obviously, aortic conditions, atheromatous coronaries, coronary occlusion, acute exhaustion of the heart muscle, cardiac pain occurring in psychoneurotic individuals or in women at the menopause without other pathology discernible, vary widely as regards prognosis and treatment. I would feel that the most important feature in discussing this paper is to simply reiterate its fundamental facts, namely that cardiac pain, irrespective of its productive mechanism, must

be the signal for searching and finding the pathological condition responsible for it in that individual.

J. EDWARD HARBINSON, M. D. (Department of Medicine, Woodland Clinic, Woodland)—In all cases of precordial pain, it is vital that we have a clear picture of the pathological conditions present, as these etiological factors determine our outline of therapy and prognosis.

In addition to the types of cases cited, we sometimes see patients complaining of heart pain whom we suspect of having some type of aortic disease. At autopsy, especially in cases of simple dilation of the aorta, the coronaries may show no evidence of disease and the heart muscle may not be materially damaged. The deficient cardiac blood supply is probably due to incomplete filling of the coronaries. Normally, the openings of the coronary arteries are so situated in the sinuses of Valsalva, that they have an adequate reservoir of blood to draw upon during the period when the aortic valves are closed. In cases of aortic insufficiency, due either to dilation of the aortic ring or to aortic stenosis, conditions are changed. The coronaries not only have an inadequate reservoir of blood to draw upon, but, in addition, the blood leaking back into the left ventricle produces definite eddy currents and probably some suction and, in non-diseased valves, the regurgitant blood may produce some deflection of the leaflets toward the walls of the aorta. Any of these conditions serve to decrease the volume of blood entering the coronaries.

When, in addition to these conditions, we have pathological constriction of the coronary, coronary sclerosis, myomalacia, or other heart muscle changes, the situation becomes very grave.

Patients often come to us complaining of precordial pain and, on examination, show negative findings, except for occasional ventricular extra systole. They insist that their complaint is pain and not a sense of irregularity or other discomfort. They do not definitely belong to any of the classes enumerated and we cannot dismiss them with a diagnosis of psychoneurosis, as the pain disappears if we are fortunate enough to be able to restore a normal rhythm with quinidine.

As emphasized by Doctor Kelly, patients suffering from heart pain cannot be given any routine type of treatment. Each case demands careful study and individual treatment compatible with the pathological changes present. The general measures cited are very important. Amyl nitrite pearls or tablets of nitroglycerine, grains 1/100 (dissolved under the tongue) may be carried by the patient at all times giving him a relative sense of security as well as being very serviceable during acute attacks in most cases.

DOCTOR KELLY (closing)—Doctor Spiro justly says that I have not considered all of the theories of the causation of angina pectoris. Albutt's belief that the aorta is the seat of the disease has never seemed to explain it to me, perhaps chiefly because in my own experience, a minority of my patients with primary angina have had aortic changes which have been demonstrable, while there has usually been definite evidence of valvular or myocardial change. Contrarywise, I have seen large numbers of patients with enormously extensive aortic disease and no history of painful attacks—sometimes a slight or severe constant aching substernal in location.

I also feel that a slight change in the diameter of a part of the aorta, or a slight bulge of its root, is a very insufficient base upon which to erect a diagnosis of angina pectoris of aortic origin.

A frequently used example of anginal pain not caused by "heart strain" is that occurring at night and wakening the patient into an attack. It is argued that this must be due to aortic disturbance because the heart muscle is certainly at maximum rest.

Is it?

I hesitate to drag in the "Dream Books" so dear to the Freudians, but I have at present two patients who have nocturnal attacks and who, on more than one occasion, have been able to remember the dream from which they awakened in an attack. Once, a street car wreck and again a fist fight, either of which indulged in by day time would unfailingly bring on an attack. We do not remember all of our dreams, but we do know that many of them induce considerable circulatory changes of such nature that the heart can in no wise be said to be at

rest. I put this forth as a tentative explanation for many nocturnal attacks—an explanation which I have not seen in the literature.

I agree fully with Doctor Cummings that we should avoid "fuzzy-mindedness," but the fact remains that patients complain of pain located in a definite place, often far from sub-sternal, and who are we, in the present state of our knowledge, to say that the impulse has spilled over in every case. I won't deny that it may have originated outside of the heart muscle in the beginning, as I feel that as yet enough certainly does not attend our knowledge of the exact nature of the disease.

I appreciate the careful discussion of this paper, which only attempted to place angina pectoris before us with a possible working hypothesis upon which to conduct treatment.

QUESTIONABLE DIAGNOSTIC METHODS

By JOHN W. SHUMAN, M. D., Los Angeles

There are more than two sides to any controversial subject, and the subject Shuman discusses is admittedly a many-faced one. This is indicated in some of the discussions on his paper.

It is logical to expect that some of Shuman's statements will produce some strong reactions. This he expects. Some may even censure the editor for permitting the frank discussion. My reply is that discussion, however frank, is welcome, so long as it maintains an impersonal character and does not endanger the cause of better medicine by washing dirty linen in public places. All writers must bear in mind the fact that California and Western Medicine is a public medium and that each issue is probably examined by several thousand non-medical people, including those who are looking for weapons to use against physicians.

Comment on the question raised by Shuman or any other will be published if it complies with the policies established for the guidance of the editor.

—EDITOR.

Medicine being made uselessly complicated and expensive.

Over-specialization not an asset to the cause of better medicine.

Good clinical judgment still the mainstay of the physician.

Standardization of laboratory and other diagnostic methods recommended.

Too many consultants more harmful than none.

DISCUSSION by T. C. Edwards, Salinas; Rene Bine, San Francisco; Dudley Fulton, Los Angeles; W. C. Shipley, Cloverdale.

FOLLOWING the World War many diagnostic clinics were formed. Fads for surveying the health of communities became prominent. It is an axiom that anything, "too prematurely born, soon withers away and dies." I believe this to be true of the activities just mentioned. We, as physicians, must not lose sight of the best interests of our patients. It is not to the best interest of the average sick individual to be examined by too many physicians. In pneumonia this is very true for too much examining disturbs the patient's rest both physically and mentally; and it is one reason why the wealthy man, suffering from pneumonia, who can afford many physicians, and thus too many examinations, has less chance for recovery than the poor patient who has only nature, assisted by his personal physician, to depend upon.

My students have had difficulty in understand-

ing my attitude in not letting them "thoroughly and painstakingly examine the pneumonia patient two and three times a day," until they have realized and appreciated the value of rest as a therapeutic agent, and have learned that inspection is more valuable than extensive percussion and auscultation in the successful management of the pneumonia patient.

The psychic effect upon the patient who is passed from one consultant to another is not for lasting good. The patient sooner or later realizes that he is no better off physically by having too many doctors. Mistakes like the following are more frequent than they should be or than they would be if direction in diagnosis and treatment were more completely centralized in one directing physician.

A man of 45 years, while paying a last visit to his daughter, was referred to a most competent radiologist 350 miles away for a series of x-ray treatments of the abdomen, for "an intestinal carcinosis springing from carcinoma of the rectum, diagnosed after surgical exploration and pronounced inoperable." The dosage was already mapped out so my technician had only to deliver the directed treatment dosage. A year or so later a doctor recalled the case to my mind, and said, "that man came back to his home town and to me, given up by all you specialists; but I gave him potassium iodid and his 'tumor masses' are all gone. I had treated his early syphilis fifteen years before."

The young doctor of today, following his year of hospital internship with its two months' laboratory service, during which time he sees "The Chief" making diagnoses from "specimen reports," enters his practice with the impression that pipettes, tubes, slides, scopes, blood chemistry apparatus and what not are essential in diagnosing disease. There is no doubt that the clinical laboratory is a most valuable aid in diagnosis, but blind credence in a test or group of tests alone leads too easily to the examiner's conviction of the correctness (?) of his diagnosis and to the selling of his opinion as a fact to the patient.

There are three classes of individuals interested in diagnostic methods. First, the honest physicians with personal interest, critical minds and dispassionate judgment. Some call these men scientific. They are intelligent, common sense observers. Hippocrates, Sydenham, and Osler were striking examples of this class which is not large enough.

The second class are physicians and persons engaged in caring for the sick, who are especially moved by sentiment; they lack proper critical sense; they seek for diagnosis to be made easy. This class is large.

The third class are those engaged in the manufacture of diagnostic instruments and their accessories. Too many of this and some of the second class not only realize, but make use of the greatest of all human weaknesses, viz., "the willingness of people to believe." The innumerable followers of cults, pathics and actics, who have little training and conceptions of diagnosis, treat only for the fee's sake, and merit no consideration here.

If we physicians cease to be such easy prey to the get-rich-quick schemes of promoters and manu-

facturers of alleged diagnostic instruments of precision and their accessories, and lose the willingness to believe that pathognomonic symptoms frequently exist, the world will be better off.

Ten years ago sero diagnosis was at its height. Pernicious anemia was "easily diagnosed" by a color index, greater than one. Syphilis was unmistakably recognized by enlarged bilateral postauricular and epitrochlear glands; and a too high blood-pressure was a cause for prognosing early death. Now Abderhalden's test is defunct; a primary anemia does not exist; it takes more than adenopathy to make the diagnosis of syphilis; and we are learning that we did not know so much about blood pressure at that time. The Wassermann test is now standardized and its limitations realized. It is a recognized fact at present that a "frank, reliable Wassermann reaction is evidence of syphilis; and that, in the absence of a syphilitic history, the diagnosis of syphilis should be made with great care; that the test should be verified by repeated tests, and that a negative Wassermann is of little value."

All new and elaborate diagnostic procedures should be standardized and given a first, second, third, fourth or no place rating in diagnostic value, depending upon their practicability and dependability. If diagnostic procedures had to undergo an evaluation similar to that of medical remedies before gaining recognition, it would be a step in the right direction. Individual physicians have their favorite diagnostic methods, but the average diagnostician, however, uses the average diagnostic methods in an average manner, and thereby his average diagnostic deductions, roughly speaking, are about 80 per cent correct. Some of the procedures in vogue that should be standardized are gastric, renal, spinal fluid and metabolic tests.

In my work gastric analyses have been superseded by radiological studies. I find the roentgen ray more dependable and less costly to the patient. Renal function tests are of no value in distinguishing uremia from other conditions, or in prognosis. Basal metabolism studies, if properly used, may give a certain amount of valuable information, but as no two men can use the same machine on the same patient and get the same deductions, I feel it is still too embryonic and too costly a procedure for practical clinical medicine. Spinal puncture is too common a procedure and is not as simple as venous puncture. The diagnosis of cerebro-spinal meningitis should be made before a puncture is thought of, and then instituted more as a therapeutic rather than a diagnostic procedure. I never make a spinal puncture unless I expect to find increased pressure or micro-organisms.

Other procedures which may be viewed along these lines are Lyon's A, B, and C bile tests, pneumoperitoneum technic, catheterization of ureters and blood chemistry. Some diagnostic procedures may be harmful because they are oftentimes performed by eager and untrained hands.

If the clinician does all the work on the patient himself, using the laboratories, the technique of which he supervises, for "findings," and then interprets the findings himself with a definite notion of their practical application, all will be well. Just

what should and should not be a routine is a matter of choice and habit. I secure history and physical examination findings and have them typewritten on a history card. Blood pressure reading and fluoroscopic examination are a part of my general physical examination, just as is testing the "station, gait, and reflexes." But I do not bismuthize and fluoroscope the gastro-intestinal tract when there are no subjective or objective symptoms of disease indicating such procedure. A record of temperature, pulse, respiration, weight, urine and blood is made for each patient. No one of these will make the correct diagnosis, and none of these is observed and entered simply to elaborate a record.

A certain diagnostic procedure which is too often used is "exploratory operation." It is the coward's flag under which he marches to make a diagnosis. By this is not meant that an "acute abdominal crisis," for example, intestinal obstruction, is not a diagnosis sufficient to call for abdominal section. But I do mean that those abdominal explorations which are meddlesome surgery may be a menace and a crime too often committed in the name of MEDICINE.

Westlake Professional Building.

DISCUSSION

T. C. EDWARDS, M. D. (Salinas, California) — Doctor Shuman's paper has more real meat in it than any I have read for a long time. What he says about frequent examination of patients is a fact.

After a definite diagnosis of pneumonia has been made, what possible benefit is it to the patient for you to "go over" his chest daily? What information can one gather from these daily percussions front and back that cannot be more satisfactorily had by referring to the clinical chart, aided by the power of observation? Vastly more good may be accomplished by making a friendly visit. Feel the patient's pulse, and as you do so, give his hand a caressing little pat, and thus let him know, as Oliver Wendell Holmes suggests, that "you are all his own." Make your mere presence in the sick chamber of more value to the patient than your medicine.

The suggestion by Shuman of having diagnostic procedures standardized is a good one. This would give the stamp of reliability where now there is frequently definite uncertainty in relation to some of these so-called aids.

Ray Lyman Wilbur has expressed the opinion that the physician of the future must stand upon a broad foundation; must be fully qualified to diagnose and treat the ills of the sick; and, above all, he will remember that the individual is a very complex entity requiring very careful PERSONAL attention.

Shuman's idea of having the physician do all the work of supervising, collating and interpreting laboratory and other findings (not delegating it to others) is in accord with Wilbur's judgment and good common sense. When this is done there will be less use for specialists.

I wish to emphasize Shuman's views about spinal puncture, exploratory operations and the like. If we take a little more time in the study of our patients, tomorrow or next day there may be such change in conditions that the "interesting" case may look altogether different; in fact may be on the road to recovery. Remember what Holmes says:

"Of all the ills that suffering man endures,
The largest fraction liberal NATURE cures!"

I wish to commend the doctor on the excellence and timeliness of this paper.

RENE BINE, M. D. (380 Post Street, San Francisco) — Some thirty years or more ago, so I was told, two recent graduates of a European medical college settled in a community where there was but one doctor, an old-timer, an old fogey, they considered him, untrained in the use

of high-power microscopes, culture media, bacterial stains, and the like. It was a question of but a short time before the community would make its comparisons, and then the old fogey's patients, and others from the surrounding parts, would crowd the waiting rooms of the two scientifically trained men.

But alas! The stupid community must have been blind. The old doctor held his patients, and the young men had plenty of time for reflection. But just as they were despairing, influenza appeared, and in a short time there was such an epidemic as to make it impossible for even three men to properly handle the situation. The young men were in such demand, day and night, that for weeks they hardly met.

Then late one afternoon, one of them came back to his room, sent for the landlady, told her he was sick, all in, possibly going to die, and please send for the old doctor, but please not to tell his chum about this, as he did not wish to hurt his feelings. Upon which the landlady replied not to worry, she would not say a word, the old doctor would be there shortly, she had just sent for him to come and take care of his friend!

Shuman evidently agrees with those of us, who, when sick, prefer to have the old doctor, or possibly a man trained by so-called "old doctors." For the good old doctors are primarily clinicians, men who question their patients, who examined them thoroughly and intelligently, whose judgment is sound, and who never lose sight of the fact that they are not treating a disease, but a patient, an individual whose mental and moral state must be taken into consideration—always.

And Shuman, no doubt, would prefer to be in the hands of the man who keeps proper case records, and who does not trust to his memory, plus a few "laboratory reports," for all of his data.

There is no doubt that in many American medical schools too much emphasis has been placed upon the newer laboratory methods. We often hear of patients being sent for Wassermann tests before histories are taken or physical examinations made. Frank Billings told me about a year ago that he had referred a patient to a hospital some time before because of symptoms suggesting an enlarged prostate. A couple of days later, visiting the hospital, he looked for his friend and found him in the chemical laboratory where every possible functional renal test was being carried out, blood tests galore, x-rays had been taken of most of his bones to rule out metastases, but no physical examination had been even started!

Repeated clinical examinations often enable one to reach conclusions in a given case; occasionally even the simple review of a history will do the trick.

I agree with Shuman that blood-pressure readings should be a routine procedure. It is a great satisfaction to be able to tell a patient, year in, year out, that his physical status has shown but little change. A routine urine examination is essential. No physician can be criticized who omits fluoroscopic examinations as a routine procedure, not to mention the fact that many patients are seen often at their homes only.

Nor can too much reliance be placed upon the "findings" of the radiologist, aye, of the best. How often does a negative report really exclude gall-stones? How often does a positive report prove duodenal ulcer, chronic appendicitis, abdominal adhesions, or even cancer? How many teeth have been unnecessarily extracted because of tiny shadows?

Doctor Shuman's suggestion that new and elaborate diagnostic procedures be standardized is a good one. It is also quite important, I believe, that the medical teachers of this country, by precept and by example, try to turn out good *clinicians*, and that at our medical meetings, and more especially in our county societies, more attention be paid to the presentation of well-studied clinical material than to the highly specialized report of a pathological rarity.

DUDLEY FULTON, M. D. (Pacific Mutual Bldg., Los Angeles)—In my opinion Shuman's very interesting paper offers no constructive criticism other than making a plea for more thoughtful analysis of clinical and laboratory findings.

Every experienced clinician agrees with the author that

there is too much test-tube, x-ray and serological influence in modern medicine. Yet who would attempt diagnostic work without utilizing the aid these diagnostic methods give when properly valued?

I believe Shuman could write a better paper covering the neglect of these diagnostic methods, as it is undoubtedly true that they are more frequently neglected than abused and improperly interpreted. A case in point: The confusion in diagnosis and treatment of the case of "Intestinal Carcinosis" he reports in this paper would probably have been avoided had a competent Wassermann test been performed.

In regard to the suggestion that diagnostic methods be standardized similarly to medical remedies and published weekly in the Journal of the American Medical Association, it should be pointed out that proper valuation of either can be demonstrated only by their application to general practice. This is the contribution of the clinician to progressive medicine and which the research worker has always solicited.

While we are willing to admit, for the sake of argument, that the art of medicine may possibly not measure up to the standards established by such famous clinicians as Hippocrates, Sydenham and Osler, yet it must be conceded that the science of medicine, as displayed by the general practitioner, manifests greater accuracy in diagnosis and, therefore, therapeutics, than ever before. We are inclined to believe that this is the result not only of more advanced knowledge of biological laws, but of the application of the latter, to everyday practice, by the diagnostic methods under discussion.

W. C. SHIPLEY, M. D. (Cloverdale, California)—Doctor Shuman has presented some very appropriate facts in his paper. There can be no doubt as to the ill effects of excessive and too frequently repeated examinations of the gravely ill, especially in pneumonias.

To my mind one good consultant, when a case demands it, is as good for all parties concerned as a far greater number.

With the average high-class medical man, a consultant is only necessary to confirm the attending physician's findings, help him in making a diagnosis and sharing in the moral responsibility.

The diagnostic clinics, while beautiful in theory, are not always perfectly satisfactory in practice.

There can be no question but that the accessory diagnostic means of x-ray and laboratory should be standardized and the simplest and most satisfactory selected for general use for no medical practitioner, no matter how keen his powers of observation and his ability to analyze the findings of his special senses, can depend entirely upon case history and clinical evidence; neither should these fundamentally important elements in the practice of scientific medicine be neglected in favor of laboratory methods.

Intelligent use of all diagnostic measures should be employed in arriving at a definite conclusion as to the cause of a patient's deviation from a normal standard of health.

SHUMAN (in closing)—Discussion greatly appreciated.

Surgical Procedures in Jaundiced Patients—A practical application is made by E. Starr Judd, Rochester, Minn. (Journal A. M. A.), of the work of McNee, van den Bergh, Aschoff and Mann to the surgical treatment of jaundiced patients. The most valuable aid in the handling of jaundiced patients is the van den Bergh test for the quantity and quality of bile in the serum. Much has been accomplished in the preoperative treatment of jaundiced patients, which means more than just the intravenous administration of calcium. Judd believes that in deeply jaundiced patients the common ducts should usually be drained with a tube, and the gallbladder should be drained if necessary, but not removed. Hepaticoduodenostomy is the procedure of choice in cases of postoperative stricture. Cholecystogastrostomy offers considerable relief in certain types of inoperable malignant diseases, and also seems helpful in cases of hepatic infectious jaundice. Multiple needle punctures in cases in which the liver is badly damaged allow a certain amount of blood and fluid to drain out, and may tend to restore the function of the liver.

Clinical Notes and Case Reports

FECAL VOMITING OF RARE ORIGIN

By C. C. ALLISON, M. B. (Toronto)

(From the National Soldiers' Home Hospital, Los Angeles)

Vomiting is a most important symptom. Persistent vomiting, though periodic in type, calls for a most thorough investigation. Fecal vomiting usually, but not always, bespeaks obstructive symptoms. For example, this patient exhibited fecal vomiting as his chief symptom, but he did not have complete obstruction. His was a vicious circle of stomach and jejunum with a fistula leading up from the colon into the latter.

CASE REPORT

No. 4986: Male, age 29. Admitted November 20, 1923, complaining of "vomiting at weekly intervals, frequent diarrhea and eructations of gas without colic."

History in Brief—Following a truck accident in January, 1919, while in the A. E. F. service, he was sent to the hospital for minor injuries, and while there a thyroidectomy was performed and he was then invalided to the U. S. A. and discharged in July, 1919, on a "SCD" (Surgeon's Certificate of Disability). One week after his discharge from the army he developed "stomach symptoms." A gastro-enterostomy was performed for "peptic ulcer," followed by symptomatic relief until July, 1923.

Physical examination revealed a tall undernourished weak man with pale skin and cyanotic lips and fingertips, and edema under the eyes; pyorrhoëa-alveolaris and multiple dental abscesses. Chest expansion was poor, the diaphragm high; the abdomen prominent with a small amount of ascitic fluid present; an incisional scar five inches long in upper right rectus with hernial protrusion.

An x-ray gastro-intestinal series showed an outline of the transverse and descending colon in the "immediate" plate. The roentgenologist, R. C. Shawhan, M. D., considered this was due to previous medication and returned the patient to the ward, advising him to return later. The ward record showed, however, that this patient had not received any medication which would cause an "opaque shadow."

The laboratory reported "occult blood" present in the stools on three examinations: A basal metabolic rate of 35; RBC 4,500,000; haemoglobin 74 per cent.

Patient was examined on May 8, 1924, by Medical Consultant John W. Shuman of Los Angeles, who reported as follows: "The gastro-enterostomy has not only served its purpose, but has become a menace. Advise that it should be taken down for this will return the food to its usual route, eradicate the ventral hernia, and give the surgeon an opportunity to clear up any pathological condition that may exist."

His progress record showed, in spite of medical management, a continuous loss of weight, frequent night sweats, frequent attacks of diarrhea, and vomiting and neuritic pains with paraesthesia all over the body. On July 10, without complaint of previous nausea, he vomited a quart and a half of feces containing hard scybalous masses.

Patient was referred to Colonel James A. Mattison, Chief Surgeon, for further consideration from the standpoint of surgical intervention. After reviewing the findings thoroughly, he decided, in view of the fact that the patient had myocardial degeneration with considerable resulting ascites, that the patient was too poor a risk for surgical intervention. He advised that it would be necessary to cut off the old gastro-enterostomy and probably do a partial resection of the stomach and do a Polya operation. Fecal vomiting again occurred on July 20, and thereafter at frequent intervals up to the time of death, August 8, 1924.

Autopsy was performed August 10, and showed the celiotomy scar attached to the side of the gastro-enterostomy by a thin strand of adhesions. The stomach was

greatly dilated, the pylorus infiltrated. The transverse colon was firmly attached to tissues involved in the gastro-enterostomy. The pylorus would barely admit a pencil, and, upon opening it, a depressed puckered scar of a healed posterior pyloric ulcer was noted. The first portion of the jejunum was attached to the posterior surface of the stomach. The gastro-enterostomy orifice was sufficiently large and showed absence of ulceration. The jejunum below the orifice was convoluted and attached to the transverse colon anteriorly. The colon lay between it and the stomach and a fistula wide enough to admit the finger was found between the jejunum and the colon at a point 1 c. m. below the gastro-enterostomy. The portion of the transverse colon immediately proximal to the gastro-enterostomy was infiltrated and stenosed so it would admit a finger with difficulty (See Figure 1 and 2.)

Other findings were: Chronic cholecystitis with adhesions to the transverse colon; chronic appendicitis; 500 cc. of amber colored ascitic fluid; high diaphragm; partial atelectasis of the lower lobe of the lung.

Points of Interest—The cause of fistula between colon and jejunum is problematical. It was definitely apparent that nothing short of cutting off the old gastro-enterostomy, re-establishing the continuity of the colon and doing a Polya or some similar operation, would have been necessary to have saved this patient. It is very evident, however, that patient was too poor a surgical risk to even consider such a procedure.

ULCERS OF THE BLADDER

By E. HAROLD KING, M. D., Los Angeles

Ulcers of the bladder may be due to injury, tuberculosis, gonorrhea, cystitis, lues, or malignant tumor. A solitary punched-out ulcer is a common type in anemic women. The ulcers may be single or multiple and perforation may occur into the prevesical space or the peritoneal cavity. The types of bladder ulcer I have seen mostly have been gonorrheal in origin. These ulcers have presented symptoms of severe pain, with bloody, turbid urine and have been slow to respond to treatment except when fulgurated. Most of the patients have refused fulguration.

It is a known fact that astounding results have been obtained from the administration of parathyroid substance in varicose ulcers of the leg and ulcers of the rectum. How this endocrine substance acts has not as yet been fully determined. It is claimed that not only does parathyroid substance regulate calcium metabolism, but also stimulates general cellular nutrition. I have used parathyroid substance, combined with calcium lactate in three cases of ulcer of the bladder and cite these cases to show the gratifying results obtained.

CASE REPORT

CASE 1. Adult male, age 34, complained of vesical tenesmus, blood in the urine, and pain during the act of urination. Cystoscopic examination revealed a large ulcer of the bladder. Ureteral catheterization showed negative urines from the kidneys. Patient had gonorrhea eighteen months ago. Treated at office with vesical irrigation of sterile distilled water until the water came away clear. This was followed by the instillation of one ounce of emulsion of silver iodide which was retained in the bladder for several hours. The accompanying cystitis was relieved, but the patient still complained of pain at the end of urination after ten days' treatment. He was admitted to hospital, put to bed, fed on green vegetables, large quantities of water and orange juice. The medical treatment consisted of soda bicarbonate grains 30, along with parathyroid substance gr. 1/20th and calcium lactate, grains 5, every three hours. At the end of six days all urinary symptoms had disappeared. A cystoscopic examination made one month later showed the ulcer had cleared up.

CASE 2. Adult female, age 26, complained of pain over right kidney and bladder. Fever ranging from 100 to 104 for over one week. Gonococcal infection three months previously. Examination showed a profuse vaginal discharge and smear confirmed the diagnosis of gonorrhea. This patient was admitted to hospital and given the same line of treatment as outlined in Case 1. Within five days the temperature was down to normal and all bladder symptoms had cleared up. This patient remained in hospital seven days. A few days later she was put

under ether anesthesia, a cystoscopic examination showed the ulcer of the bladder had healed and to clear up the specific endometritis the uterine cervix was dilated, the endometrium and cervical canal were swabbed with equal parts of carbolic acid and iodine and the vaginal walls treated in the same manner. An iodoform gauze pack (5 per cent) was introduced into the vagina and removed after twenty-four hours. This patient is now free from all bladder symptoms and has no vaginal discharge.

CASE 3. Adult male, aged 54. Complained of vesical pain and painful micturition for two months. Wassermann four plus. Given course of Salvarsan and mercury, but the bladder symptoms were not relieved. The cystoscope revealed an ulcer of the bladder just outside the trigone. This patient would not consent to fulguration of the ulcer, but did go to bed and followed the dietetic and medical treatment outlined. He is now free from all pain after three weeks' of treatment.

SIGNIFICANCE OF THE COLLOIDAL PROPERTIES OF GELATIN IN SPECIAL DIETARIES

By THOMAS B. DOWNEY, Ph. D.

(Of the Mellon Institute of Industrial Research,
University of Pittsburgh)

An examination of the dietetic possibilities of gelatin from a chemico-physiological standpoint reveals a number of properties which would make this unique food product a valuable addition to special dietaries, particularly those in which milk forms the sole or major portion. In such dietaries gelatin functions as a protein food to the extent of the utilization of its amino acids by the body, and in addition possesses marked activity as a protective colloid and emulsifying agent. Practical observations in clinics and hospitals, as well as experimental work in laboratories, indicate that these characteristic properties of gelatin as a colloidal substance exert a most significant influence in promoting digestion and absorption of certain types of foods.

The importance of this colloidal activity of gelatin, where fed in conjunction with dairy products, has been demonstrated by the writer in feeding tests with the albino rat. Shortly after weaning, the young from several litters were divided into two groups; one group received pasteurized whole milk as its sole diet, the other pasteurized whole milk containing 1 per cent of gelatin. Observations, extending over a period of six months, showed that the growth and physical well-being of the group fed on gelatinated milk was markedly superior to animals fed on the plain milk diet. The increased growth was accomplished on smaller food consumptions. In fact, during the early growth period for equivalent gains in body weight the animals on gelatinated milk consumed about 23 per cent less food than the group on plain milk.

Another striking illustration is found in the writer's experiments with ice cream. Over a period of seven weeks it was observed that a group of rats fed on an exclusive diet of ice cream, containing 1 per cent of gelatin, gained no less than 25 per cent more in body weight than was the case with their brothers and sisters whose diet was plain ice cream. For equivalent gains in body weight, the food consumptions of the group fed on the gelatin-containing ice cream were much less. Smaller percentages of gelatin resulted in proportionate improvements. It is important to note in this connection that the better nutritional status of the gelatin ice cream group after a number of months on the diet was reflected in continued health and growth, and in increased bone development and reproduction in several cases.

It should not be presumed that the observed improvements of the dairy products are due entirely to the added protein value of the gelatin, but possibly more to the protective colloidal and emulsifying effects that it confers. The digestive processes are essentially colloidal phenomena, whereby fats, carbohydrates, and proteins are ingested in the colloidal conditions and changed by the various enzymes to degradation products capable of absorption by the body. To accomplish the

formation of these simpler substances, the enzymes must come into intimate contact with the food particles. If, perchance, the food particles are present as large tough masses, as is the case with cow's milk coagulating under the influence of the hydrochloric acid and rennin in the human stomach, the contact surface of the enzymes with the food is limited and gastric digestion is delayed or impaired. Various specialists have described experiments in vitro as well as with humans which show that the coagulation of cow's milk by acid and rennin is prevented or modified in character in the presence of relatively small amounts of gelatin. This effect is spoken of as protective colloidal action, and it is interesting to note that gelatin is one of the most efficient of all human protective agents. Gelatin is also a good emulsifying agent and it is quite probable that it aids the secretions of the alimentary apparatus in the emulsification of fats.

In discussing the digestibility of milks, Chapin says that those animals whose stomachs form the larger percentage of the digestive tract and their digestion is largely gastric produce milks that form tough curds, as for example, the cow. In contrast is the human, whose stomach forms only about 20 per cent of the digestive tract. Human milk curdles in light flocculent masses. It has been pointed out by Alexander that human milk contains a natural protective protein in large amount, which is present in small amount in cow's milk. It would seem, that the addition of such a protective agent as gelatin to cow's milk would make it particularly suitable for infants, and such has been found to be the case, as is testified to in pediatric literature.

In like manner, gelatin has been shown to be of value in other dietaries composed largely of dairy products. For example, Hawk reports that the addition of gelatin to the milk-egg diets of tuberculosis patients resulted in decided nutritional improvements with the majority of the cases tried.

The experiments described suggest the advantages that are to be derived by the utilization of gelatin in other dietaries. The protective colloidal and emulsifying action of gelatin promotes the digestion and absorption of various types of foods. It is also misleading to assume that gelatin as a protein is of insignificant food value.

Feeding tests by McCollum and by Osborne and Mendel have shown that, with certain cereal grains, gelatin is exceptionally well utilized, presumably through its high content of the amino acid lysine. Also, with milk proteins gelatin is of value, as has been found by Sure. In combination with milk in the liquid form, it is believed, however, that the colloidal properties are of greater significance.

[EDITOR'S NOTE: Announcements regarding a well-known brand of gelatin are found monthly in our advertising pages.]

Shoe Dye Poisoning—C. W. Muehlberger, Madison, Wis. (Journal A. M. A., June 27, 1925), has found a total of forty-seven cases of poisoning from shoe dyes reported in the literature. Of these, twenty-five resulted from dyes containing nitrobenzene, and twenty-one from dyes containing anilin. The toxic substance responsible for one case was not stated. One of the cases of nitrobenzene poisoning resulted fatally. All the reported cases of anilin poisoning from shoe dyes are from European sources, while all those of nitrobenzene poisoning are from the United States. The nine cases reported by Muehlberger are the first of anilin poisoning from shoe dyes to be reported in the United States. The outstanding symptoms of poisoning exhibited in these cases are: marked cyanosis, weakness and vertigo followed by rapid pulse, headache, vomiting, somnolence and chills. The only treatment required is the removal of the shoes and rest in bed until the cyanosis disappears. Oxygen inhalation is without effect on the cyanosis. Digitalis medication is without avail and is not indicated. The chemical analyses of four commercial preparations of black shoe dye are given. All these were found to contain either nitrobenzene or anilin. The only way that this type of poisoning can be adequately prevented is by state or national health regulations prohibiting the manufacture and sale of toxic shoe dyes. It is recommended that nitrobenzene and anilin be replaced by nontoxic solvents in order to eliminate the danger of poisoning.

EDITORIALS

THE LANE MEDICAL LECTURES

The 1925 Lane Medical Lectures will be given on October 5, 6, 7, 8, 9. They are by Doctor Vittorio Putti of the Rizzoli Institute, Bologna, Italy. They all have to do with problems of orthopedic surgery. They are by a remarkable man with a remarkable background—one of the great leaders in this specialty of medicine.

Every physician in Western America ought to hear these lectures and meet Doctor Putti. We talk a great deal about post-graduate review work. Here is an opportunity provided by the foresight of a California physician, and President Wilbur of Stanford University issues an invitation to doctors to avail themselves of this privilege.

The full program, with a brief illustrated biographical sketch of the lecturer and a brief description of the wonderful institute in which he works, will occupy this space in the September issue of CALIFORNIA AND WESTERN MEDICINE. This preliminary note is only a suggestion so that physicians desiring to attend these lectures may have ample notice of the time, and plan their work accordingly.

DIGNIFYING LEGAL MEDICINE AND ETHICS IN MEDICAL EDUCATION AND PRACTICE

Since early in its existence the College of Medicine and Surgery of the University of the Philippines has had a Department of Legal Medicine, at first with a part-time professor and executive head and later with a full-salaried professor and several assistants. As in all other departments of that splendidly organized medical education, hospital and health service center, the head of the department in the school is not only ex-officio head of the corresponding department in the hospital, research laboratories and elsewhere, but wherever such departments can be extended to be of use in the practical work of the city and insular governments, that extension has been made.

The most recent report of Professor Sixto de los Angeles outlines an illuminating expansion and a satisfactory service in both teaching and practice of the great problems involved in legal and ethical medicine, which we have not seen exemplified elsewhere.

The department is now more than ten years old, and it not only teaches the problems connected with legal medicine and ethics to undergraduate students and graduate students of medicine, but the department serves every probable medico-legal patient admitted to the Philippine General Hospital or any of its services from the time of admission until the case is disposed of finally in the courts. All cases of medico-legal jurisprudence that arise through the police departments, courts or any other departments of the city or insular government at Manila, are, by affiliation, promptly referred to this department of the medical school, and the officers of the depart-

ment take an active interest in assisting the courts and officers in a fair adjudication of the matter.

For this purpose the department maintains its own specially equipped laboratories, laboratory workers and technicians of other kinds necessary to carry forward this enormously important and growing branch of medicine.

By action of the Regents of the University of the Philippines, this department of legal medicine also constitutes the same department for the College of Law of the same university. Its faculty is made up with a full-time professor at the head and with a number of specialists, including attorneys, doctors, chemists, toxicologists and similar part-time instructors and a number of technicians.

Every other department in this school is organized along the same broad lines, but it is unusual to see such consideration given to legal medicine, and it is interesting to note that after ten years of experience the practical service of such a department to hospitals, courts, police bodies and government in general, as well as to the public, more than compensates, even in money value, for the cost of operating the department.

Persons interested in co-ordinating educational and practical ideals in organization and management of medical and health institutions can learn something from the organization in our far distant possessions.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION REVISES AND EXTENDS ITS PROGRAM.

No more important or far-reaching movement in the progress of better health has been announced in recent years than that shown in the recent report of the Council on Medical Education and Hospitals of the American Medical Association. Heretofore the Council has concerned itself chiefly with the regulation of instruction of undergraduate medical students; the listing of schools in which satisfactory instruction is given and the accrediting or approving of hospitals acceptable for fifth year (intern year) instruction of medical students. More recently, the Council has wisely extended its field to include the supervision and approval of schools and institutions preparing to teach graduate medicine in general, including those teaching the specialties, and hospitals and other health agencies that desire to supply acceptable residencies and instruction in the various specialties to graduate students in medicine. All of these movements have been carefully matured, and if wisely promulgated, as they undoubtedly will be, will mean much to the cause of better health for the citizens of the United States.

HOSPITALS APPROVED FOR INTERNS

The essentials in a hospital that desires to be approved for interns have been modified and extended. Hereafter only the general hospitals will be so approved, and the conditions of approval have been strengthened and made more definite. It would take too much space to reproduce or analyze these new essentials here, but all physicians, hospitals, and other health agencies interested in the problem should write to the Council at 535 North Dear-

born street, Chicago, for a copy of the new recent publication.

HOSPITALS APPROVED FOR RESIDENCIES

The Council has made a clear distinction between the fifth year medical student or intern, as he is most commonly called, and the more advanced graduate student or hospital resident, as he is now officially termed. Special hospitals and others not eligible because of lack of variety of material for approved standing for interns are now approved by the Council for second and later year graduate students of medicine. This is an important move and one that is going to take considerable time to be widely and fully appreciated. Hospitals not eligible for approval for interns, but which are prepared and desire to give special graduate instruction to still more advanced students, should make their applications for accredited standing for this purpose. Applications may be sent directly to the Council in Chicago, or they may be sent, as before, to the Hospital Betterment Service of the League and California Medical Association at 593 Market street, San Francisco.

GRADUATE MEDICAL SCHOOLS AND TEACHING INSTITUTIONS

The Council has already prepared a list of approved graduate schools of medicine, and of hospitals which have made satisfactory provision for hospital residents in certain specialties in which the hospital is giving high-grade work. Stanford University School of Medicine and the University of California graduate division are the only two institutions so far accredited this way for California. There are two different kinds of graduate instruction above the intern year: One kind is given by a recognized teaching institution with adequate approved hospital evaluations, and the other kind is given by a hospital accredited for graduate instruction or residencies. Most of the students who will continue their studies beyond the required fifth or intern year are naturally those preparing themselves to practice a specialty. The approval of either a graduate school or a hospital for this purpose, therefore, is determined largely upon its ability to give real instruction in a satisfactory manner in one or more of the recognized specialties of medicine. The whole movement is one in the right direction. It fixes once and for all the essential fact that the fifth year medical student is still an undergraduate student. It provides opportunities—approved opportunities, whereby students of medicine who wish to continue their studies with a view, either to becoming specialists or to otherwise advancing their knowledge of medicine, may have the same safeguards that have proved themselves so effective for the younger undergraduate in medicine.

None of these propositions, excellent as they are, takes care of the biggest and most vital problem confronting medicine, namely: the preparation of a better general practitioner. This, in the opinion of this editor, must be provided for, and I believe could be done in a most practical manner by accrediting or approving small hospitals of less than 100 beds for residents in the second and later years of graduate medical study. It is these smaller hospitals that

are on the firing line and whose staffs and attending physicians in general are in immediate contact with the rural populations of our country. It is to them, and through them, and in no other way that the young physician may fit himself for the general practice of medicine. Such accredited standing for these hospitals may require either residence in the hospital or an apprenticeship in the office of one of the physicians practicing in that hospital and in the surrounding rural community. When the Council on Medical Education and Hospitals have added this additional step to what they have already so well done, the scheme of medical education will become more rounded, practical, and as complete as can be expected. That such a step will come is as inevitable as is the progress of medicine. There are a considerable number of hospitals of from twenty to seventy-five beds in California, for example, in which just as good medicine is being practiced by men just as able as is being practiced anywhere else in any community, and, furthermore, the staffs and attending physicians of all of these hospitals are the burden-bearers on the outer edges of medicine among our more or less rural citizens where our great advance in the future must be expected.

Congenital Hypertrophic Pyloric Stenosis—Four hundred and fifty-four cases of congenital hypertrophic pyloric stenosis in which the Fredet-Rammstedt operation was performed are reviewed by R. W. Bolling, New York (Journal A. M. A.). During the last ten years, there has been a gradual reduction in mortality, which is attributed not only to an increase in the proportion of favorable cases, but also to certain changes in the care of patients before and after operation. Of this entire series, sixty-seven died, a mortality of almost 15 per cent. The general mortality for the first 175 cases of this series was 17.1 per cent, and there was very little difference in the results in private and in ward patients. The contrast, however, is striking in the 279 patients operated on since January, 1920. Forty private patients were operated on with one death, and 239 ward patients with thirty-six deaths. All deaths in the hospital following operation are classed as operative deaths. Thirty-three patients died in collapse in from two to seventy-two hours after operation. Twenty-two patients died in from five to twenty-six days. In two instances necropsy disclosed acute gastro-enteritis. In two patients, bronchopneumonia was found. In another dying on the twenty-first day, a small hematoma was found at the site of the pyloric wound. Severe infection of the wound from a pre-existing omphalitis was the cause of death in two cases. Other necropsies were negative. Hemorrhage was responsible for the death of five patients: Two of these died from bleeding from the abdominal wound and two from bleeding in the wound in the pylorus. One, apparently a true hemophiliac, died on the third day from continuous oozing from the pylorus and the abdominal wall. Six deaths occurred from peritonitis. Two were in cases in which the duodenum had been accidentally opened. Two occurred early in the series, when the operation was modified by passing a bougie through the pylorus by means of a small opening in the stomach. One patient died twelve hours after an operation for an acute intussusception, which developed on the second day after operation. Bolling concludes that the Fredet-Rammstedt operation is simple, curative and permanent in its result. Convalescence is rapid, and the infant returns almost at once to normal development. In view of the results obtained by surgery in this series during a period of more than ten years, there appears to Bolling to be little justification for a delay which turns a good operative risk into a bad one, substitutes a long accidental convalescence for a brief, uneventful one, and fails to restore promptly a growing infant to a satisfactory state of nutrition at an important period in its development.

The Month With The Editor

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

I See By the Papers That—

Another doctor has a \$20,000 judgment against him for "malpractice." The plaintiff had charged that his wife died as a result of an operation claimed to have been "unskillfully and erroneously performed."

Some doctors insure their homes against fire and their motor cars against everything, but are still too shortsighted to protect themselves against the increasing and unavoidable legal hazards of their profession.

—A San Francisco doctor "announces" that after "a year's experimentation at San Quentin penitentiary and a year's study in Europe," he has "learned an operation that corrects deviating eyes." The newspaper articles carries the pictures to prove it.

—Doctor Sir Arbuthnot Lane again occupies the headlines. This time he is helping the cancer quacks.

During recent years he has managed so as to be quoted as a sort of endorser by more than one species of cultist, but this cancer stuff he is feeding to the press will do untold harm.—See Mr. Ford's Dearborn Independent of June 20 for some of the details.

—The doctors of San Mateo, Burlingame and Hillsborough refused to give free treatment to the children of the well-to-do residents of these exclusive residential districts.

It appears that a school nurse had rounded up some 150 of these "poor little rich children" and called upon the doctors to render them "free" service, which the doctors quite properly refused to do.

—Some surgeons are adding to their notoriety by tattooing their initials on the patient's body. Let us hope that the tattooing is not always placed too close to the scar.

—A doctor's name was "posted" in his club for non-payment of his account. The doctor fastened to this posting a neatly typed sheet, headed "What's sauce for the doc is sauce for all the following" (here he listed the club members who owed him for services).

Whether "doc" got his money or not is not stated.

Doctor, Have You Noticed that practically all welfare movements requiring the services of physicians are promoted and administered by lay organizations that dictate medical policies?

It is quite possible, believes the editor of Ind. Med. Jour. that some of the paid employes of these organizations, who are basking in the limelight, would not be so enthusiastic if they lost some of their powers to dictate to doctors.

Will They Take the Hint?—"The child is not the mere creature of the state," declares the U. S. Supreme Court in declaring unconstitutional the Oregon School law.

This ought to be a blow to those uplifters who are meddling into the private, personal and sacred affairs of that fundamental unit of civilization—the home.

But will it? It will not. These meddlers will go on trying to formulate laws, rules and what not calculated to give them control over mating and the desirable and natural consequences of mating even to the extent of blazoning the most sacred of connubial matters upon official and other incorrectly called "confidential records."

One paragraph of the *unanimous* decision of the Supreme Court which should be engrossed and kept constantly before educational authorities, public health doctors and "welfare" organizations, reads:

"The fundamental theory of liberty upon which all

governments in this union repose, excludes any general power of the state to standardize its children by forcing them to accept instruction from public teachers only. The child is not the mere creature of the state; those who nurture him and direct his destiny have the right, coupled with the high duty, to recognize and prepare him for additional obligations."

That Effective Apple—"Didn't I see you going down the street the other day with an apple in your hand?"

"Quite so, old chap. I was going to call on the doctor's wife.

DISEASE IS AN IMPEDIMENT TO THE BODY, but not to the will, unless the will itself chooses. Lameness is an impediment to the leg, but not to the will. And add this reflection on the occasion of everything that happens; for you will find it an impediment to something else, but not to yourself.—Epictetus.

—This fundamental fact, like many others, is called obsolete by some of our modern faddist teachers and philosophers (?).

COMMENTS BY AUTHORS AND READERS—

—"If my paper should be published, I suggest discussion by Dr.——, Dr.—— and Dr.——. I am not at all sure that these gentlemen will agree with my opinions; nevertheless their decisions will be honest and of value."

—"I am sorry indeed that my overworked condition has made me so tardy in returning my manuscript and that you have had to write me so many times. Assuring you of my appreciation of your forbearance and considering myself constructively admonished, I am,"

—"When I returned the other day from a vacation to my office I found the May number of the CALIFORNIA AND WESTERN MEDICINE awaiting me. I have always been interested in medical history and I want to tell you and your co-workers how much I enjoyed the historical number. I would like to have one more copy for filing in my library."

"You surely publish one of the best journals in the U. S.—none better and sound editorials."—M. D., Indianapolis.

After Over 300 Years of Effort vital statistics of sorts are available for only about 80 per cent of our people.

If we show such speed in making progress where there is no controversy, how long will it take us to secure some of the "uniform laws" some are advocating about controversial subjects?

Suppose we should secure a uniform vaccination law, for example, would it be better enforced for that reason? Assuredly not.

Most health laws, "uniform" or otherwise, are largely disregarded. From 40 to 60 per cent of tuberculosis reported, for example, is reported from morgues. This in spite of long standing drastic laws on the subject.

The laws requiring the reporting of syphilis and gonorrhea are the jokes of the age.

What School Children Are Taught—An official government pamphlet based upon a study of what is being taught our school children about health, quotes, among others, the following extracts from the teachings in various states:

"Blood is of no use except as it is kept in circulation."

"The purpose of adenoids is to protect the child against disease."

"When the nose and throat are healthy, they produce a germicidal secretion which rids the incoming air of nearly all its bacteria."

But, why quote more?

Bunking the Public by dishonorable exploitation of false value is the keystone of a substantial share of current publicity.

Unfortunately this method is being employed by some who claim to be leading medical thought.

—“Hubby—‘What are you taking that patent medicine for—you’re well, aren’t you?’
“Wife—‘Of course I am; but the advertisements of this dope are too attractive not to give it a trial.’”

Indiana Has a New Law which permits insurance companies to write policies of \$2500 or less *without medical examination*.

Doctors would do well to digest this fact in connection with the editorial in the February, 1925, issue of this magazine.

There is more to this movement than is visible to the nearsighted.

—But to go back to apples a moment, “Abe Martin says it’s jest about got so a doctor a day is cheaper’n apples.”

“Corns” was the Subject of a Hunterian lecture before the Royal College of Surgeons some time ago.

Dyspepsias, hemorrhoids, flatulence and a lot more so-called trivial illnesses should be similarly dignified and restored to the attention of physicians.

—In the aggregate these “minor ailments” constitute over 90 per cent of the limiting and partially disqualifying infirmities of man.

They supply the “fodder” for the “faddists.”

Recent References to Chiropractors as the “I knead you doctors” seems to us as particularly fitting.

It May Be Significant that the A. M. A. House of Delegates passed unanimously a resolution calling upon the government to remove the restriction upon the amount of alcohol a doctor may prescribe for a patient within a given time limit.

In the same connection it is of more than passing interest that the new forthcoming edition of the U. S. Pharmacopeia again admits both whisky and brandy among the approved drugs.

Many Thoughtful People are beginning to wonder if mass intellect has sunk to such a level that it will interest itself in nothing but exploited sensation and salaciousness and will accept no expression of opinion that does not flatter the prejudices and complacencies of the thoughtless and subliterate.

—Perhaps it is only a “dark of the moon” phase of a social cycle we are going through. Let us hope so. In the health field in any event, the “health fairy” has grown up into the Chamber of Commerce bathing beauty.

“The Jealous Doctor and the hungry lawyer are the two main causes of malpractice suits,” concludes the very active medico-legal committee of the Wayne County (Mich.) Medical Society after fourteen years of experience.

—The committee’s figures show the significant fact of an annual average of more than one threat to sue for each 100 doctors.

Nothing Will So Quickly Kill a really valuable procedure as to propagate a lot of wild and extravagant claims for it which are not and never could be justified by the facts.

—Too many are forgetting that this truth applies to matters pertaining to health as certainly as it does to “get rich quick procedures.”

Isn’t It Stimulating to Read that Ivan Petrovitch Pavlov, the Dean of Physiologists, is still at work in his researches, and, although over 75 years old, is producing some of his best work?

Let us hope that world affairs will soon be so that the output of this remarkable Russian may be again

more widely available than it has been during recent years.

The Total Number of Accidents reported to the California Industrial Accident Commission for 1924 was 206,131. Of these accidents 645 caused death, 1319 caused permanent disability and 87,982 caused temporary disability lasting longer than the day of the injury; 116,185 were no-disability accidents but *all required skilled medical treatment*.

Golfer—Doctor, you remember you recommended golf to take my mind off my work?

Doctor—Yes.

Golfer—Well, can you prescribe something now to get it back again?

PLAY HAS BEGUN TO DOMINATE PHYSICAL EDUCATION, believes John Sundwall. “One serious difficulty, however, with the play movement,” continues this authority, “is that it has become largely emotional, and when emotions dominate any movement there are dangers ahead.”

—Several new healing cults have already grown out of the so-called “physical education” movement.

—When the Romans tangled up one end of their play movement with medicine and the other end with work, the movement perished and took much of their civilization with it.

A negro was trying to saddle a fractious mule.

“Does that mule ever kick you, Sam?” asked a bystander.

“No, suh,” said Sam, “but he sometimes kicks whar I jes’ been.”

The Doctor of the Future—Advance sheets from the report of the Rockefeller Foundation show concern for the future of physicians:

The Foundation states that, “Probably three-quarters of all doctors today are general practitioners. There are people who assert that this type of physician is doomed; that he will disappear because he cannot compete with the specialist on the one hand and with preventive and social medicine on the other.

“Such an outcome is to be viewed with concern. The well-trained, properly equipped, experienced general practitioner of ability, character, and personality is a fundamentally valuable person.

“The stimulating philosophy of individualism, with its insistence upon independence, initiative, and ambition,” continues the report, “seems to be embodied in the general practitioner, who will survive only if he can win confidence and make a living.”

Troublesome Tonsils—It requires precisely the same education, training, experience and judgment to say intelligently that the tonsils of any child should come out, that is required to perform the operation.

The day is about over—except in backwood communities—when teachers and other technicians are going to disturb families and communities by advising tonsillectomies for school children.

Inadequately educated technicians would do less injury to health by doing the operation after the diagnosis had been made by a physician, than they do by making disturbing diagnoses and finding someone who will operate on their say so.

Reflections of a Medical Teacher—One of the greatest and most enduring professional pleasures of a medical teacher, believes J. G. Beardsley (Jour. Med. Soc. of N. J.), is the satisfaction of observing the deserved success that comes to former students. One of the disappointments in a teacher’s life is the realization that a proportion of the medical men whom one has watched, guided and admired as students have gradually degenerated into performing their professional work in a manner and by methods that are not a credit to their profession, their former teacher or to themselves.

Medical Economics and Public Health

Another "National" Organization is out to Prolong Life—For a Fee—This time it is San Francisco that is the home of a "league" of specialists who are out to prolong the lives of all members by "periodical health examinations." The "profit and loss" account of this, as well as the other more or less similar corporations, will reflect the *business* acumen of its promoters. One of our good doctors says that when he reflects upon the activities of any of these "life prolonging" movements organized for *business* he always thinks of the old limerick:

"There was an old man who said, 'Hush!'
'I perceive a young bird in that bush.'
When they said, 'Is it small?'
He replied, 'Not at all!'
" 'It is five times the size of the bush! ' "

"The N. Y. Life Extension Institute," notes the Journal of the Indiana State Medical Association, editorially, "with its profitable scheme of conducting health examinations with the assistance of medical men who are merely the go-betweens, and which came in for criticism at the hands of the Judicial Council of the A. M. A. at the Chicago session, is whining. In a letter sent broadcast the Institute says that the Judicial Council of the A. M. A. is not exhibiting a spirit of justice and fairness toward the Institute, and in a rather long argument, the basis of which is the fact that 'the Institute was established and has had the cordial support and endorsement of many of the leaders of preventive medicine and public health work,' it winds up with the boast that despite the unfavorable opinion expressed by the Council, the Institute has received no resignations of any of its examiners, but, on the contrary, the Institute is increasing the number of its examiners by about two hundred per month, the bulk of whom are Fellows of the American Medical Association.

"We are not surprised," continues the editor, "to know that there are a certain number of medical men whose services can be purchased by the Institute and who are unwilling to relinquish the fees paid, even though they recognize the principle of the transaction as being inimical to the best interests of the medical profession as well as the public. We, therefore, desire to support the Judicial Council in its contention, and we approve the statement made in the Council's report to the House of Delegates."

Numerous Inquiries about the alleged virtues of compressed air, hot air, and air from the corn growing Middle West—air in tanks, by radio and in "blimp"—'tis sure cure for diabetes and what not, induces us to reply by quoting from the New York World the following story:

"The son of a poor New York woman went to California to seek his fortune. He worked hard and bought an orange grove, but bad luck overtook him and he lost everything. To cap the climax he got word that his mother was dying. Anxious to reach her bedside, he rode his bicycle all the way back to New York—for he was too poor to buy a railroad ticket. He reached his mother's home in time to find her breathing her last, and as he had no place to put his bicycle he brought it into the room where she was lying. Suddenly, and without warning, one of the tires blew out and the marvelous California air, which he had pumped into it, was diffused in the atmosphere, with the result that his mother recovered on the spot."

"Why the government should enter into competition through subsidized physicians and hospitals with physicians and hospitals that are not subsidized, and that depend for their very existence on the patronage they received from the sick and injured, is not apparent," says an observation by the Trustees of the American Medical Association.

"It has not yet authorized hungry, cold and inade-

quately clothed veterans to draw their supplies from the Army and Navy commissary departments," continues the observation, "nor has it authorized veterans who are inadequately housed to take up their dwellings on naval and military reservations. Protection from hunger, cold and exposure are as necessary to health and happiness as is medical and hospital care in time of illness and injury; yet the government has not entered into subsidized competition with the grocer, the coal man, the dealer in men's furnishings and the landlord."

"The situation," concludes our trustees, "may almost be stigmatized as communistic medicine in its most militant form, endeavoring to edge its way into American life under the cloak of patriotism."

"The public is strongly inclined to buy the advertised article, be it a phonograph or a chiropractic treatment. We do not advocate lowering, in any respect, the honorable code of ethics which has been our pride. The individual practitioner must not be advertised. The institution of medical practice must be advertised and in an adequate, dignified way which it deserves."—(Bulletin Wayne County Med. Society.)

What the Rural Nurse Owes the Rural Doctor is the title selected by "A Red Cross Public Health Nurse" for a most illuminating article in the June issue of The Pacific Coast Journal of Nursing.

After reading it, as every doctor and nurse should, the reason for a pen name is obvious.

Doctors and public health nurses are constantly drifting further apart, not because of themselves, but because of the meddlesome activities of groups of new and mostly incompetent "healthers."

"A LARGE PROPORTION of our population has sought the care of clinics and welfare associations and more and more is the practice of medicine invaded by governmental, social and welfare organizations, to the ultimate harm, as we believe, not only to the profession, but also the people. Commercialism on the part of the individual doctor will promote that movement which we recognize as a menace."—(Earp. A. M. A. Bulletin.)

"THE COMMERCIALIZING of medicine by laymen, however much it may offer from an economic point of view," believes the Cleveland Bulletin, "places the controlling factors in the hands of those who, though honest, are not by experience qualified to conduct such a business. They may employ regularly licensed physicians on a salary, but the control still rests in the hands of those who have no personal contact with, or experience in, the intricate problems of diagnosis and treatment."

"Why do doctors give away \$100,000,000 worth of free service a year in hospitals, clinics, home and office treatment, while other men give away nothing?" asks the Nebraska Med. Jour.

If the service of a plumber tinkering around a broken water pipe in a home is worth \$4 an hour, how much, one of our advertisers wants to know, is the service of a physician, ministering to a broken body, worth?

"Although all public health nurses agree that doctors should be the leaders in preventive medicine, I have recently asked myself," says "A Red Cross Public Health Nurse" (Pac. Coast Jour. of Nursing), "if, in practice, we rural nurses give the doctors the opportunity to lead which we grant them in theory. Do we not, instead, decide what should be done and then expect the doctors meekly to fall in line? As I review my own failures, I find the cause in many cases was this very attitude on my part."

"Let him who doubts the fact that doctors are the leaders in preventive medicine come to the rural districts. He will soon learn that the extent of the local doctor's approval is the limit to which the nurse may carry her ideals."

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
W. T. McARTHUR, M. D.....President-Elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

ABSTRACTS FROM THE MINUTES OF THE COUNCIL, FIFTY-FOURTH ANNUAL SESSION, CALIFORNIA MEDICAL ASSN.

One Hundred and Fifty-second Meeting—Held in Manzanita Cottage, Yosemite Lodge, Yosemite National Park, California, Sunday, May 17, 1925, at 8 p. m.

Present—Doctors Parkinson, MacGowan, Ewer, Alderson, Kinney, Kiger, Edwards, De Lappe, Smith, McLeod, Hamlin, Kress, McArthur, Gibbons, Curtiss, Pope and General Counsel Peart.

Absent—Doctors Beattie, Coffey, and Bine.

Minutes of the Council—On motion of McArthur, seconded by De Lappe, it was resolved that the minutes of the 150th and 151st meetings of the Council as mailed to each member thereof be approved.

Minutes of the Eighty-first Meeting of the Executive Committee—The secretary read the minutes of the eighty-first meeting of the Executive Committee, which were approved as read.

Minutes of the Eighty-second Meeting of the Executive Committee—The secretary read the minutes of the eighty-second meeting of the Executive Committee, which were approved as read.

Permanent Convention Headquarters—Harlan Shoemaker of Los Angeles, chairman of the Committee on Permanent Convention Headquarters, being present by request, reported that his committee had made three trips to that part of the coast exactly one-half way between Los Angeles and San Francisco; that nothing further had been done inasmuch as very little interest had been shown by the San Francisco members, but that his committee still thought the project was worthy of some further consideration and ought to be kept in mind.

Action by the Council—On motion of Alderson, seconded by Hamlin, it was

Resolved, That the report of the Committee on Permanent Convention Headquarters be received; and that the Committee be continued, and further that the thanks of the Council be extended to the Committee for the very large amount of work it has done.

Keene Memorial Committee—The secretary presented a letter from Mr. Louis A. Reeg of Placerville, stating that the work of the Committee on the Keene Memorial was completed.

Action by the Council—On motion of Kiger, seconded by Gibbons, it was

Resolved, That the final report of the Committee on the Keene Memorial be received; and that the committee be discharged with the thanks of the Council.

History of the California Medical Association—The secretary reported that Doctor Phillip King Brown, secretary of the Medical Historical Committee of the San Francisco County Medical Society, had informed her that his committee had accomplished nothing. She then read a letter from Doctor Hans Barkan, secretary of the West Coast Medical Historical Society, stating that nothing had been accomplished by his Society.

After discussion, it was the sense of the Council that the matter be postponed until the meeting on Monday afternoon, May 18.

Bunnell Memorial Committee—Emmet Rixford of San Francisco, chairman of the Committee on the Bunnell Memorial, being present by request, submitted the following report:

"Your Committee, appointed at the 1923 meeting of the California Medical Association on the Memorial to Doctor Lafayette Houghton Bunnell, is pleased to report that it has caused to be made a plaque, cast in bronze, twenty-four inches in diameter, commemorating the naming of Yosemite Valley by Doctor Lafayette Houghton Bunnell, a member of the Mariposa Battalion which entered the Valley in March, 1851, in pursuit of the Yosemite Indians, the members of the Battalion being the first white men known to have entered Yosemite. The plaque, designed by Mr. Paul J. Fair, U. S. Forest Service, represents a grizzly bear, by which is idealized the inhabitants of the Valley as well as the Valley itself, viewing with curiosity, if not surprise, the advent of the caduceus, symbolizing the medical profession; this, with appropriate lettering, setting forth the fact of the discovery of the Valley and the suggestion for its name made on that occasion by Doctor Bunnell.

"This plaque, through the co-operation of the Department of the Interior, is to be erected on a boulder at the site of the first and principal camp of the Mariposa Battalion in the Valley, near Bridal Veil meadow. The plaque is to be unveiled with appropriate ceremonies and dedicated to Doctor Bunnell on Tuesday, May 19. It has been arranged that the unveiling shall be done by the president, Doctor Granville MacGowan, and addresses will be made by Mr. W. B. Lewis, Superintendent of Yosemite National Park, on behalf of the Department of the Interior, National Park Service, U. S. Government; Mr. Francis P. Farquhar, on behalf of the Sierra Club, and Doctor Emmet Rixford, chairman of the Committee.

"The expense incurred for this purpose was:

"To the sculptor, Mr. Paul J. Fair, \$100; to the artist who made the cast, Mr. Fred T. Storey, \$100; photographs to be submitted to Mr. Stephen T. Mather, Director of National Park Service, \$5; Total, \$205, less \$50 contributed by Doctor Howard A. Kelly of Baltimore, Maryland, to the Bunnell Memorial. Total paid by the Society, \$155. To this will be added some small sum for expense incurred in erecting the plaque on the boulder and traveling expenses of Mr. Farquhar.

"The Committee would suggest that the House of Delegates pass a resolution of thanks to Doctor Howard A. Kelly, first, for the suggestion that such a monument be erected to Doctor Bunnell, and secondly, for his generous contribution of \$50.

"With this final report the Committee begs to be discharged.

"(Signed) Emmet Rixford, M. D., Chairman.

"Saxton T. Pope, M. D.

"Egerton Crispin, M. D."

Action by the Council—On motion of McArthur, seconded by De Lappe, it was

Resolved, That the final report of the Committee on Bunnell Memorial be received; that the recommendations of the committee be concurred in; and further that the Committee be discharged with the thanks of the Council.

Committee on Prenatal Care—Henry A. Stephenson of San Francisco, sub-chairman of the Committee on Prenatal Care, being present by request, informed the Council that the general chairman, Doctor Reginald Knight Smith of San Francisco, had called a meeting of some twelve obstetricians of the bay cities and had later appointed two sub-committees; the first under Henry A. Stephenson to handle the material on Prenatal Care, and the second under William Palmer Lucas to handle the material on the Care of the Baby. He further stated that the replies to the proposed pamphlet had arrived too late for his committee to give the matter the consideration it deserved, and believed that the Council should give Doctor Smith an opportunity to go over the material again and finally dispose of the reports. The question was then fully discussed.

Action by the Council—On motion of Alderson, seconded by De Lappe, it was

Resolved, That the Council, having heard the report of Doctor Henry A. Stephenson, sub-chairman of the Committee on Prenatal Care, concurs in the recommendation that the material be returned to the Committee; and that the Committee be requested to reconsider it and present a final report at a subsequent meeting.

Clinical Prizes—The Chair advised the Council that the Committee on Clinical Prizes had not yet been appointed, and that the Chair felt the amounts of the prizes were too small. The Council was informed that the editor also wished to establish a prize, and the Chair stated that this prize might well be competed for by the members of those state medical associations for which CALIFORNIA AND WESTERN MEDICINE is the official organ.

The whole matter was then considered and fully discussed.

Action by the Council—On motion of Kress, seconded by De Lappe, it was

Resolved, That the action of the Council at its 148th meeting, held at Long Beach, November 8, 1924, whereby three clinical prizes were established in the sums of \$100, \$75, and \$50, be rescinded; and that two prizes of \$150 each be offered—one for a paper on original research and one for a paper on a clinical subject; and that these prizes be open to the membership of the California Medical Association only, and be competed for at the 1926 Annual Convention; and further that the scope of the material be determined by the committee.

Councilor Visits—The Councilors made the following reports on their visits to the various county societies in their respective districts:

Kiger—Second District. I visited every county society in my district but Orange County. These societies appear to be doing well. Ventura, which I helped revive last year, is going very well; Santa Barbara is very good and Los Angeles is still fighting the \$100 tax.

Smith—Seventh District. I visited only Alameda, having been away for six months and so have no report to make on the other counties. Will visit the other counties next summer.

Kinney—First District. Have had Imperial over to meet with San Diego, and their organization is going very well.

Edwards—Third District. Monterey and San Luis Obispo counties are doing very well. The meetings are well attended and the visit of the councilor is doing considerable good, and many questions are asked particularly regarding Industrial Medicine and the new Medical Society. San Luis Obispo seemed to be more alive than my own county society (Monterey), which is not as active as I would like. Probably one reason for this is that the county is so widely separated. Taking it on the whole, I believe that the visit of the councilor was a good thing and had a beneficial effect.

McLeod—Ninth District. As far as my own county society is concerned, Sonoma is in good shape. I had a joint meeting last week of Sonoma, Mendocino and Lake counties, and learned that Mendocino is not functioning very well, particularly in winter, because of the great distances and bad roads. I tried to get in touch with Marin and have a joint meeting, and expect one very soon. I find that it is better to have joint meetings. Have never had the pleasure of a meeting with Solano. Humboldt is such an out-of-the-way, hard place to reach that I cannot give much report on it.

Curtiss—Councilor-at-Large. Being a councilor-at-large I have no district, but, realizing that Riverside is such a long ways from San Diego, I have tried to keep in touch with that county. It is doing very well.

De Lappe—Fourth District. I visited every functioning society in my district—Fresno, Kings, Madera, Merced and Mariposa. The meetings were all well attended. The conditions are not good, however, as out of 335 physicians in that district, only 175 are members of the California Medical Association and only twelve are members of the Medical Society of the State of California. It seems to me that such a condition requires some active solicitation. I was unable to learn the reason for such a small membership in the California Medical Association. As far as the new Medical Society is concerned, they say, "What is the use of buying something for \$10, for which you have already paid \$25 or more?"

Parkinson—Eighth District. In reporting, I desire to say that I have been derelict. I arranged for a meeting in Woodland; one in Sacramento and one in Chico, and one farther in the north. I did not accomplish very much owing to the illness and death of Doctor James, which was followed by the serious illness of my boy, and then a death in my family. Will do better next year. Will arrange to get the northern counties in Redding, and the Marysville men at Chico. The District is doing well—the medical population is increasing very materially. Will try and present a better report next year.

Scientific Programs of Hospital Staffs—The vice-president, Harry E. Alderson of San Francisco, raised the question of the scientific meetings now being held by the attending hospital staffs, which were greatly inter-

fering with the meetings of the county medical societies.

After a general informal discussion, it was the sense of the Council that the chair appoint a committee of one to outline a course of action to overcome this situation and present such plan at the next meeting on Monday afternoon, May 18.

The chair appointed George H. Kress of Los Angeles as this committee of one.

Amendments to Constitution and By-Laws — The secretary presented the proposed amendments to the Constitution and By-Laws, and informed the Council that the constitutional amendments would have to be presented to the House of Delegates at the 1925 Session, thereafter published in the Journal twice during the coming year and then acted upon by the House of Delegates at the 1926 Session; but that the amendments to the By-Laws could be presented at the First Session of the House of Delegates tomorrow evening and acted upon at the Second Session on Wednesday evening.

It was the sense of the Council that each member thereof be furnished with a copy of the proposed amendments for further consideration; and that action on the matter be referred over to the next meeting on Monday afternoon, May 18.

Report of the Council—The chairman submitted his annual report for consideration and approval before presentation to the House of Delegates. He stated that his report would not be presented before the General Session on Monday morning as in the past, but only before the House of Delegates.

It was the sense of the Council that the consideration of the annual report of the Council to the House of Delegates be postponed until the next meeting, Monday afternoon, May 18.

Adjournment—There being no further business, the Council adjourned to meet in the same place at 2 p. m., Monday, May 18, 1925.

One Hundred and Fifty-third Meeting—Held in Manzanita Cottage, Yosemite Lodge, Yosemite National Park, California, Monday, May 18, 1925, at 2 p. m.

Present—Doctors Parkinson, MacGowan, Ewer, Kinney, Kiger, Edwards, De Lappe, Coffey, Smith, McLeod, Hamlin, Kress, McArthur, Gibbons, Curtiss, Pope and General Counsel Peart. Alderson was present, and immediately excused as he was scheduled to present a paper before the Dermatology Section.

Absent—Doctors Beattie, Bine.

Walter V. Brem's Paper—The secretary submitted a letter from Doctor Walter V. Brem of Los Angeles, in which he stated that he would be unable to attend the Convention on account of Mrs. Brem's illness, and, therefore, would be unable to present his paper on "The History and Problems of Disease" before the General Session on Thursday morning, May 21.

Action by the Council—On motion of Gibbons, seconded by Kiger, it was

Resolved, That a reader be selected to present Doctor Brem's paper on Thursday morning, and that the Chair appoint a committee of one to make such selection.

The Chair appointed William H. Kiger of Los Angeles as this Committee of One.

Bank Signatures—The secretary reported that the Union Trust Company had requested that a third person be authorized to sign checks for the Association, and that the Executive Committee at its last meeting considered the matter and recommended that, "in the absence or illness of either the Chairman of the Council or the Secretary, the President or the President-Elect be authorized to sign checks."

Action by the Council—On motion of De Lappe, seconded by Gibbons, it was

Resolved, The action of the Executive Committee of the California Medical Association at its eighty-second meeting, held in the offices of the Association, 1016 Balboa Building, San Francisco, April 30, 1925, in authorizing the President or the President-Elect to sign checks in the absence or illness of either the Chairman of the Council or the Secretary be hereby ratified, confirmed and approved.

National Board of Medical Examiners—The secretary reported that thirty-one states already recognized the National Board of Medical Examiners; and that the California State Board favored such recognition, pro-

vided it could be legally recognized; and that the California Board had tried to have the law amended but the measure was thrown out in the Committee of the Assembly. The secretary then read a letter from the California Board of Medical Examiners to Doctor Martha M. Bacon of Los Angeles, which stated in part:

"There is merit in your suggestion that some plan of universal registration should be devised, and it is our understanding that considerable effort and study has been directed along this line for several years. The only outcome so far has been the organization of the National Board of Medical Examiners, whose requirements are much higher than those exacted by practically every State of the Union. An Act of Congress is the only method whereby it is possible to arrange universal registration."

After consideration, it was the sense of the Council that, as nothing could be done at this time, the matter be referred to the Executive Committee for further investigation and report.

Industrial Medical Practice—Sol Hyman of San Francisco, chairman of the Committee on Industrial Medical Practice, being present by request, read the report of his committee, which was then thoroughly discussed by all present.

Action by the Council—On motion of Kress, seconded by Hamlin, it was

Resolved, That Doctor Sol Hyman be requested to incorporate in his report, after consultation with his committee, specific recommendations as to just what they wished done; and that the amended report be submitted to the Chairman of the Council and the General Counsel before presentation at the First Session of the House of Delegates this evening.

History of California Medical Association—The question of the appointment of a Committee on the Preservation of the History of the California Medical Association was raised, and the chair announced that a committee of three, with power to collaborate with other members of the Association, would be appointed later.

Amendments to Constitution and By-Laws—The general counsel submitted the following amendments to the Constitution and By-Laws, which were thoroughly discussed: (These were published in full on page 896 of the July, 1925, issue of CALIFORNIA AND WESTERN MEDICINE, which see.)

Action by the Council—On motion of Coffey, seconded by Kress, it was

Resolved, That the amendments to the Constitution and By-Laws as prepared by the General Counsel be approved; and that such amendments be referred to the House of Delegates with the recommendation of the Council that they be adopted.

Report of the Council—The chairman submitted the proposed "Report of the Council," which was then considered. It was the sense of the Council that the chairman be instructed to include a paragraph on "Income Tax Deductions" and "Permanent Convention Headquarters" in this report.

Financial Statements—Morton R. Gibbons of San Francisco, Acting Chairman of the Auditing Committee, submitted a brief report on the present status of the financial conditions of the California Medical Association and CALIFORNIA AND WESTERN MEDICINE for the information of the Council.

Place of 1926 Meeting—Dudley Smith of Oakland extended to the Council a cordial invitation from the Alameda County Medical Association and the City of Oakland to hold the 1926 Annual Convention in Oakland, the home of the President-Elect, Edward N. Ewer.

The secretary then read letters from the Alameda County Medical Association, the San Diego County Medical Society and the San Francisco Convention and Tourists' League, inviting the California Medical Association to hold its 1926 meeting in Oakland, San Diego and San Francisco, respectively.

Action by the Council—On motion of Smith, seconded by Gibbons, it was

Resolved, That the invitation of the Alameda County Medical Association be accepted and that the 1926 Annual Convention of the California Medical Association be held in Oakland.

Doctor Kinney then advised the Council that San Diego would request a meeting at Coronado at a later date.

Scientific Programs of Hospital Staffs—The Committee of One, George H. Kress of Los Angeles, acting under instructions received at the last Council meeting, reported that it seemed desirable to keep the programs of general hospital staffs from overlapping with the programs of county medical meetings, and that, after consultation with other members, his committee desired to present the following resolution:

"Whereas, The scientific programs of the attending staffs should concern themselves especially with the diseases and injuries of patients in such hospitals; and the attending staff scientific programs should not take the semi-abstract or literary trend that has long been and must necessarily continue to be a natural part of the scientific programs of county medical units; and

"Whereas, Our county medical societies are the constituent units of organized medicine in our state, and the development of organized medicine is absolutely essential to the protection and further growth of both the scientific and material interests of medicine in California; therefore be it

"Resolved, By the Board of Councilors of the California Medical Association, that the attention of the members of the constituent county units, who, at the same time, are members of attending hospital staffs in their respective communities, be called to the importance of not overlapping or interfering with proper scientific activities of both these highly important expressions of medical activity and development; and that your Board of Councilors presents these suggestions for the consideration of program committees of attending hospital staffs, so that these basic facts, which are of so great importance to county societies and attending staffs, may be constantly kept in mind."

Action by the Council—On motion of Smith, seconded by Kiger, it was

Resolved, That the resolution submitted by Doctor Kress' Committee be adopted; and that it be sent to all county medical units and to all hospital staffs.

Application for Associate Membership—The secretary presented an application for associate membership in the C. M. A. from Doctor Charles N. Leach, who is connected with the Rockefeller Foundation at Montgomery, Alabama.

It was the sense of the Council that, in accordance with the proposed changes in the Constitution and By-Laws, Doctor Leach be advised that he must make application for associate membership through some component county society.

Delinquency in State Association—The secretary advised the Council that the State Association considered its members delinquent on March 1, deprived them of their Journal on April 1, and that the A. M. A. considered them delinquent on April 1, whereas many of the county societies did not consider their members delinquent until much later in the year; in fact, Los Angeles not until November 1. She then stated that this variance in delinquency dates between the county societies and state association was causing much misunderstanding and resentment on the part of the general membership, and that she felt something should be done to correct it. The matter was then thoroughly discussed.

Action by the Council—On motion of Smith, seconded by Coffey, it was

Resolved, That the action of the Council at its 143rd meeting held in Los Angeles, May 11, 1924, and as contained in Minute 29 thereof be rescinded; and that all county units be instructed that all members of the California Medical Association and, therefore, all members of the component county societies who have not paid their dues on March 1 of each year shall be dropped from membership in accordance with the Constitution and By-Laws of the California Medical Association; and further that all component county societies be instructed to amend their constitutions to correspond with the Constitution and By-Laws of the California Medical Association.

Amendment to Constitution of California Association of Medical Social Workers—Request from the California Association of Medical Social Workers for ratification of an amendment to their constitution was pre-

sented, and referred to the general counsel for consideration and recommendation.

Adjournment—There being no further business, the Council adjourned to meet in the same place at 2 p. m., Tuesday, May 19, 1925.

One Hundred and Fifty-fourth Meeting—Held in Manzanita Cottage, Yosemite Lodge, Yosemite National Park, California, Tuesday, May 19, 1925, at 2:40 p. m.

Present—Doctors Parkinson, MacGowan, Alderson, Kinney, Kiger, Edwards, De Lappe, Coffey, Smith, McLeod, Hamlin, Kress, McArthur, Gibbons, Curtiss, Pope and General Counsel Peart.

Absent—Doctors Beattie, Bine and Ewer.

Walter V. Brem's Paper—Doctor Kiger, committee of one appointed at the last Council meeting, informed the Council that Doctor Roy W. Hammack of Los Angeles, who is connected with Doctor Brem's Clinic, would read Doctor Brem's paper on "The History and Problems of Disease" before the General Session on Thursday morning.

Amendments to Constitution of California Association of Medical Social Workers—The general counsel reported that the matter of proposed amendments to the Constitution of the California Association of Medical Social Workers would have to go before the Advisory Council of that Association; and that the members of the Council of the C. M. A. were members thereof.

Action by the Council—On motion of McArthur, seconded by Kress, it was

Resolved, That the matter of the proposed amendments to the constitution of the California Association of Medical Social Workers be referred to the Executive Committee with power to recommend action by the members of this Council when the Advisory Council of the California Association of Medical Workers meets to consider the question.

Status of A. J. Pacini of Chicago—The secretary reported that, after the program had gone to press, Doctor H. J. Ingersoll of Los Angeles had requested that Doctor A. J. Pacini of Chicago be given a place on the program; that, upon investigation, she was informed that Doctor Pacini was a very well posted man and able to give something of value to the Association; and that, accordingly, the doctor was placed upon the program of the California Association of Physiotherapists.

The secretary then stated that two members of a company advertising in the Journal had just informed her that Doctor Pacini was in the employ of the Victor X-Ray people (also Journal advertisers) and that they objected very strongly to Doctor Pacini's appearance on the scientific program; and further that they had been advised by the secretary to submit a written protest to the Council on the matter. This written protest was then read, and the question fully considered by the Council.

Action by the Council—On motion of Kress, seconded by Coffey, it was

Resolved, That the question of Doctor A. J. Pacini's appearance on the program of the California Association of Physiotherapists be referred to a Committee of Two, consisting of the Chairman of the Council and the general counsel, for consultation with Doctor Pacini; and further that a written statement be secured from the doctor safeguarding the rules and regulations of the California Medical Association in the matter of presentation of papers at an annual convention.

Commercial Representatives on State Programs—The question of representatives of commercial organizations being allowed space on the Section Programs was considered in view of the criticism of Doctor Pacini's appearance on the program of the California Association of Physiotherapists. It was the sense of the Council that a Committee of One be appointed by the chair to draft a resolution for presentation at the next Council meeting on Wednesday, May 20.

The chair appointed Doctor T. C. Edwards of Salinas as this Committee of One.

Hotel Headquarters for 1926 Meeting—The secretary presented a wire from the Hotel Oakland requesting that that hotel be made Hotel Headquarters for the 1926 Convention. It was the sense of the Council that the wire be placed on file for consideration at the proper time.

Inspection of Yosemite Hospital—The secretary ex-

tended an invitation to the Council from Doctor Claude H. Church to visit the Yosemite Hospital. There being no objection, it was the sense of the Council that the members thereof inspect the Yosemite Hospital at the end of this Session.

Permanent Convention Headquarters—The question of Permanent Convention Headquarters was again considered, and it was the sense of the Council that it hold its next meeting in Los Angeles in the fall, a special meeting be held with the Los Angeles County Medical Association to consider Permanent Convention Headquarters and Optional Medical Defense; and that when the Council next meets in San Francisco the same questions be presented before the San Francisco County Medical Society; and further that, if possible, the Council hold a meeting in the central part of the state during the year.

Reports on Association Activities—Dudley Smith of Oakland raised the question of the state office furnishing each Councilor with a copy of what the state office wishes brought before the various county societies throughout the year. After a general discussion, it was the sense of the Council that the secretary be instructed to furnish each Councilor, from time to time, with an outline of such matters as, in her judgment, should be presented to the county medical societies.

Adjournment—There being no further business, the Council adjourned to meet in the same place at 2 p. m., on Wednesday, May 20, 1925.

One Hundred and Fifty-fifth Meeting—Held in Manzanita Cottage, Yosemite Lodge, Yosemite National Park, California, Wednesday, May 20, 1925, at 2 p. m.

Present—Doctors Parkinson, MacGowan, Ewer, Kinney, Kiger, Edwards, De Lappe, Coffey, Smith, McLeod, Hamlin, Kress, McArthur, Gibbons, Curtiss, Pope and General Counsel Peart.

Absent—Doctors Beattie, Bine and Alderson.

Permanent Convention Headquarters—Harlan Shoemaker of Los Angeles, chairman of the Committee on Permanent Convention Headquarters, being present by request, reported further on the work of his committee and the desirability of having permanent convention headquarters for the State Association. The question then fully discussed by all present.

Action by the Council—On motion of Kress, seconded by De Lappe, and unanimously carried, it was

Resolved, That, having heard the report of the Committee on Permanent Convention Headquarters, it be the sense of the Council that a permanent location or home at which Annual Sessions of this Association could be held seems highly desirable.

Instructions to Committee on Permanent Convention Headquarters—The Council then thoroughly considered and discussed the feasibility of devising some plan whereby the Association as a whole or as individual members might handle a proposition such as a permanent home.

Action by the Council—On motion of McArthur, seconded by Gibbons, it was

Resolved, That the Committee on Permanent Convention Headquarters be requested to prepare a plan or method whereby property at any point can be acquired; and how such property can be administered while it is being held for the benefit of the Association.

House of Delegates Sessions—The question of scheduling no section or other meeting on the nights of the meetings of the House of Delegates was raised by Councilor Kress and thoroughly discussed.

Action by the Council—On motion of Kress, seconded by De Lappe, it was

Resolved, That the Council rule that, as regards General Sessions, House of Delegates Sessions and League Meetings, no Sections' meetings be permitted except with the special consent of the Council.

Section Papers—The president-elect, Edward N. Ewer of Oakland, advised the Council that there is a general complaint throughout the State regarding the non-publication of papers presented at Annual Sessions, and stated that he felt something should be done about it:

Action by the Council—On motion of Ewer, seconded by Smith, it was

Resolved, That the secretary be instructed to correspond with the chairman and secretaries of all Sections, suggesting that, on behalf of the Council, the number of

papers for presentation at Annual Sessions be curtailed wherever possible, and pointing out why such curtailment is necessary, particularly with a view to shorter papers; and further that a synopsis of all papers must be submitted to the State office for examination by the Committee on Scientific Program before presentation at an Annual Session.

Personnel of Committee on Scientific Program—The question of the personnel of the Committee on Scientific Program was raised and, after a general discussion, on motion of Kress, seconded by McArthur, it was

Resolved, That the general counsel be requested to prepare an amendment to the Constitution and By-Laws changing the character of the personnel of the Committee on Scientific Program, and the method of its election.

Status of A. J. Pacini of Chicago—The Chairman advised the Council that, in accordance with instructions received at yesterday's meeting, he and the general counsel had conferred with Doctor A. J. Pacini of Chicago and Doctor H. J. Ingersoll of Los Angeles regarding the character of the paper he was to present that evening before the California Association of Physiotherapists; that Doctor Pacini had stated he had no intention of violating the rules of the C. M. A. and had voluntarily written and signed the following letter:

"Dr. James H. Parkinson,
"Chairman, Council, California State Medical Society.

"Dear Dr. Parkinson:

"In accepting an invitation to discuss the subject of Ultra violet radiation before one of the sections of the State Medical Society, I am keenly mindful of the imperative necessity that all allusions to matters which might be interpreted as having commercial taint be completely occluded from remarks. This is not different from the situation which I have many times before encountered on similar occasions with many other State Medical Societies, and it is, therefore, perfectly agreeable to me to subscribe entirely to the wishes suggested by the council. It was, and is, my intent to refer only to such scientific researches as I have had to do with in consequence of my position as Director of the Department of Biophysical Research of the Victor X-Ray Corporation of the General Electric Company.

"No remarks which I shall make will be published by me nor by the Corporation which I represent, nor will they be given to anyone unless it be by the expressed wish of the Council.

"Very truly,

"A. J. PACINI (Signed).

"May 19, 1925."

It was the sense of the Council that the letter furnished by Doctor A. J. Pacini of Chicago was satisfactory; and that the secretary be requested to place it on file for future reference.

Commercial Representatives Debarred from State Program—T. C. Edwards of Salinas, as the Committee of One appointed at the last Council meeting on Tuesday, May 19, submitted the following resolution:

"Whereas, The Council deems it unwise and indelicate that officers, employees, agents or other representatives of commercial corporations, companies or firms be allotted space on the program of the California Medical Association, and so advises; therefore be it

"Resolved, That the Chairman of the Committee on Scientific Program of the California Medical Association be hereby instructed that, in future, no representatives of commercial companies be permitted space on any program at an Annual Session of the said California Medical Association."

Action by the Council—On motion of Kiger, seconded by Gibbons, it was

Resolved, That the resolution as submitted be adopted.

Place of 1926 Meeting—The secretary presented wires from Mayor John L. Davie and the Oakland Chamber of Commerce inviting the California Medical Association to hold its 1926 meeting in Oakland. The wires were referred to the secretary for reply in due course.

Adjournment—There being no further business, the Council adjourned to meet in the same place at 2 p. m. on Thursday, May 21, 1925.

One Hundred and Fifty-sixth Meeting—Held in

Manzanita Cottage, Yosemite Lodge, Yosemite National Park, California, Thursday, May 21, 1925, at 2 p. m.

Present—Doctors Parkinson, MacGowan, Ewer, Alderson, Kinney, Kiger, Edwards, Smith, McArthur, Gibbons, Curtiss, Pope and General Counsel Peart.

Absent—Doctors De Lappe, Beattie, Coffey, McLeod, Hamlin, Bine and Kress.

Adjournment of 1924 Council—On motion of McArthur, seconded by Gibbons, it was

Resolved, That the 1924 Council adjourn sine die; that the 1925 Council convene; and that the secretary call the roll.

Present—Doctors Parkinson, Ewer, McArthur, Kinney, Kiger, Edwards, Smith, Kress, Gibbons, Curtiss, Pope and General Counsel Peart. Doctor Alderson was also present.

Absent—Doctors De Lappe, Beattie, Coffey, McLeod, Peers, Bine, Catton and Shoemaker.

Election of Chairman—On motion of Ewer, seconded by McArthur, it was unanimously

Resolved, That James H. Parkinson of Sacramento be elected Chairman of the Council to succeed himself for the ensuing year.

Resignation of Councilor McArthur—William T. McArthur of Los Angeles tendered his resignation as Councilor-at-Large in view of his election as President-Elect of the Association, which was accepted by the Council.

Councilor-at-Large From Los Angeles—On motion of McArthur, seconded by Kiger, it was unanimously

Resolved, That Harlan Shoemaker of Los Angeles be elected Councilor-at-Large to fill the vacancy caused by the resignation of William T. McArthur, whose term expires in 1926.

Absence of Councilor Peers—The chairman reported that Doctor Robert Peers of Colfax had informed him before leaving the Valley that morning, that he did not know his name was to be presented to the House of Delegates for nomination as a Councilor-at-Large or any other office, and, therefore, would be unable to attend today's Council meeting.

Appointment of Secretary—On motion of Kiger, seconded by McArthur, it was unanimously

Resolved, That the Council desires to record its appreciation of the fact that it will be honored in the secretarial chair by Doctor Emma W. Pope of San Francisco; and further that the present salary be continued.

Appointment of Editor—On motion of McArthur, seconded by Kiger, it was unanimously

Resolved, That William E. Musgrave of San Francisco be reappointed to succeed himself as editor of CALIFORNIA AND WESTERN MEDICINE for the ensuing year at a salary of \$1 per annum.

Appointment of Auditing Committee—The chair appointed as members of the Auditing Committee for the ensuing year Doctors Rene Bine and Morton R. Gibbons of San Francisco, stating that Doctor Gibbons would serve as Acting Chairman until Doctor Bine is able to resume his work.

Appointment of Committee on Arrangements—After consideration, it was the sense of the Council that President Ewer be allowed further time in which to appoint the 1926 Committee on Arrangements.

Fall Council Meeting—The date of the fall meeting of the Council was discussed, and it was the sense of the Council that this matter be referred to the Chairman of the Council and the Secretary for decision; and that the meeting be held in the south late in September or early in October. It was also decided that, as usual, an open meeting be held on the evening of the Council meeting to consider Industrial Medicine and any other subjects; and further that a joint meeting with the local society be held the preceding evening to discuss Optional Medical Defense and any other matters; and further that this joint meeting be held on the regular meeting night of such county society.

Re-Distribution of Councilor Districts—The recommendation of the Reference Committee regarding the re-distribution of Councilor Districts was considered. It was the sense of the Council that the matter be kept on the Council docket for consideration at each meeting; and further with the understanding that Orange County be transferred from the First to the Second District and

that Kern County be transferred from the Second to the Fourth District.

Industrial Medical Practice—The recommendations of the Committee on Industrial Medical Practice and the Reference Committee regarding "rules and regulations" in such practice was considered.

Action by the Council—On motion of Gibbons, seconded by Kiger, it was

Resolved, That the matter of Industrial Medical Practice be referred with power to act to the Executive Committee with the recommendations of the Reference Committee regarding rules and codes in such practice for research and carrying out the instructions of the House of Delegates; and further that the Chairman of the Committee on Industrial Medical Practice, Sol Hyman of San Francisco, be present at such meetings of the Executive Committee; and further that when such rules and regulations and codes are in shape that Ray Taylor of Los Angeles, chairman of the Los Angeles Section of Doctor Hyman's Committee, be invited to discuss the matter with the Executive Committee.

Yosemite Hospital—The resolution, submitted to the House of Delegates by Doctor R. G. Dufficy of San Rafael, requesting an appropriation for the Yosemite Hospital, was thoroughly considered; and it was the sense of the Council that a special letter of transmittal be prepared by Doctor Morton R. Gibbons and the general counsel.

Action by the Council—On motion of Ewer, seconded by McArthur, it was

Resolved, That the resolution on Yosemite Hospital be referred to Doctor Morton R. Gibbons and the General Counsel for consideration and submission of a letter of transmittal for approval by the Executive Committee; and further that this resolution be forwarded to each United States Congressman and Senator and the officers of the National Park Service.

Recognition of Delegates—The question of certification and recognition of delegates at House of Delegates' meetings of the California Medical Association was thoroughly considered; and it was felt that none but the duly elected delegate or his alternate should be seated.

It was the sense of the Council that the matter be referred to the Executive Committee for investigation and change in the Constitution and By-Laws in accordance with the rules and regulations of the A. M. A.

Annual Sessions—The president-elect, William T. McArthur of Los Angeles, raised the question of the number of section meetings during the annual convention, which was fully discussed by all present, together with the question of the personnel of the program committee.

It was the sense of the Council that the Committee on Scientific Program should also include the secretaries of the main sections; and that the secretary be empowered to seek their assistance in the preparation of the annual program; and further that the secretary be instructed to write all section secretaries with reference to holding joint scientific meetings and their business meetings, wherever possible, at luncheons.

Address by President-Elect—The Chair called upon the president-elect, William T. McArthur of Los Angeles, who expressed his appreciation of the honor conferred upon him.

Legal Address at Annual Meetings—The general counsel stated that, if the Council felt it was sufficiently worth while, he would have a representative of his legal staff address the Association at the annual-session next year. It was the sense of the Council that such a suggestion should be carried out.

Optional Medical Defense—Councilor Kress of Los Angeles submitted the following notice regarding Optional Medical Defense, which he suggested should be referred to county societies for publication in black type in the various bulletins of such county societies:

"Have you secured the optional defense furnished by The Medical Society of the State of California? It gives you defense in malpractice suits by the attorneys of the California Medical Association. You owe it to yourself to secure this protection. Address request for information, or check for yearly coverage (\$10) to Dr. Emma W. Pope, secretary, 1016 Balboa Building, San Francisco."

The secretary was instructed to write all county secre-

taries asking them to publish this notice on all printed matter issued by their county society, and requesting that this notice be published in a different and blacker type; and further that such notice be published in each succeeding issue for 1925.

Adjournment—There being no further business, the Council adjourned to meet in the South sometime in the fall.

SECTION ACTIVITIES OF THE C. M. A. AT THE 1925 ANNUAL SESSION

(Continued from the July issue, page 894. Abstracts from Minutes received too late for that issue.)

Dermatology and Syphilology Section—This section held the usual three meetings under the chairmanship of George D. Culver, San Francisco; Hiram E. Miller, San Francisco, secretary. The scientific meeting was carried out very much as published. Many of the papers, carefully discussed and edited, will appear during the year in CALIFORNIA AND WESTERN MEDICINE.

The chairman's address on "A General Consideration of Susceptibility to Skin Diseases" was published in the July issue.

At the business meeting, Moses Scholtz, Los Angeles, was elected chairman; C. E. Schoff, Sacramento, vice-chairman, and Samuel Ayers, Los Angeles, secretary, for the ensuing year.

In discussing plans for the next meeting it was suggested that a symposium on Ultra-Violet Light Therapy and one on some phase of syphilis would be desirable.

Those attending these meetings included:

Harry Alderson, George F. Koetter, Moses Scholtz, J. C. Pickett, C. E. Schoff, H. E. Miller, George Culver, E. K. Stratton, Norman Epstein, Albert Meads, R. V. Lee, Brown, I. C. Sutton, Yates, Samuel Ayres, Howard Morrow, John Ruddock, Frank Baxter, Rea Ashley, Shirsper, Gustave Taubles, and twenty-seven others whose name we were unable to obtain.

Obstetrics and Gynecology Section—Three meetings of this section were held under the chairmanship of P. O. Sundin, Los Angeles; secretary, J. W. Sherrick, Oakland.

May 18—The regular program, embracing a symposium on Eclampsia, was carried out. Chairman Sundin read his address upon The Etiology of Eclampsia.

H. A. Stephenson, San Francisco, read a paper on Laboratory Aids in the Diagnosis and Control of Eclampsia. This paper was discussed by H. M. Ross of Los Angeles.

Hans Von Geldern, San Francisco, read a paper on Recurrent Toxemia.

Margaret Schulze, San Francisco, read a paper on The Conservative Treatment of Eclampsia. This was discussed by E. N. Ewer of Oakland, who emphasized the excellent results of conservative treatment, favoring the rotunda method and advised against any use of M. S., but suggested elimination, starvation, etc.

J. C. Irwin, Los Angeles, read a paper on The Role of Cesarean Section in the Treatment of Eclampsia.

These papers were discussed by J. Vruwink, Los Angeles, who emphasized the conservative attitude, and, with regard to magnesium sulphate, reported excellent results in a series of cases. H. M. Ross, Los Angeles, reported excellent results with magnesium sulphate, and cited several illustrative cases.

May 19—The second meeting, with Dr. R. H. Ramsey, chairman of Pediatrics Section, in the chair, was held in conjunction with the Pediatrics' Section. A Symposium on Birth Injuries was presented.

The paper on Cranial and Intracranial Injuries from the Standpoint of the Obstetrician by F. M. Loomis, Oakland, was read by J. W. Sherrick.

R. H. Kuhns, San Francisco, read a paper on Symptoms and Diagnosis in Infants; Clinical Significance in Later Years.

H. C. Naffziger, San Francisco, read a paper on the Surgical Management of Birth Injuries. General discussion followed.

Henry Dietrich, Los Angeles, read a paper on Mongolian Twins.

May 21—At the third meeting, Chairman P. O. Sundin

appointed A. B. Spalding, San Francisco, H. A. Stephenson, San Francisco, and Michael Creamer, Los Angeles, on the nominating committee. They suggested that the chairman and secretary be appointed from the same locality in order to facilitate the necessary arrangements for programs, conferences and other matters that may arise during the year. J. W. Sherrick, Oakland, was nominated for chairman, and J. A. Sperry, San Francisco, for secretary. This was put in the form of a motion and carried.

There being no further business the regular program was carried out. This consisted of a Symposium on Pelvic Relaxation and Prolapse.

A. W. Meyer gave a paper and lantern slide demonstration on Some Points in the Anatomy and Mechanics of the Pelvic Floor. Discussion by Olga McNeile, Los Angeles.

John Vruwink, Los Angeles, read a paper on Pre-disposing Factors in Pelvic Relaxation and Prolapse. Alice Maxwell, San Francisco, opened the discussion.

Michael Creamer, Los Angeles, read a paper on Benign Lesions of the Cervix in Association with Pelvic Relaxation and Prolapse. Discussion was opened by Shaw, Los Angeles.

Frank Lynch's paper on The Problem of Partial Prolapse with Cystocele and Rectocele in Young Women was read by Alice Maxwell, San Francisco. H. A. Stephenson, San Francisco, discussed this paper.

A. B. Spalding, San Francisco, read a paper on The Treatment of Procidentia. This was illustrated by lantern slides and statistics in 400 cases. J. A. Sperry, San Francisco, opened the discussion. The program was then thrown open to general discussion.

ALAMEDA COUNTY

Alameda County Medical Association (reported by P. S. Nusbaumer, secretary)—At the regular meeting of the Alameda County Medical Association held June 15, 1925, R. G. Van Nuys read a paper, entitled "Living Anatomy: A Roentgen Study of Stomach, Liver and Colon in 1000 Healthy Adults," in which he stated that these studies give a new picture of the normal positions of these organs. The positions of the viscera in the upright and horizontal positions are compared. Van Nuys believes that the anatomy of the viscera, based on a study of the dead, loses most of its value and gives students many wrong concepts of visceral form, position and relations. The doctor claims that the anatomy of the viscera should be taught as found in the living. He finds low positions of the stomach and colon to be the most common in normal adults, and says the use of the term gastropptosis and coloptosis is seldom justifiable.

In "Notes on the Interpretation of Blood Chemical Analyses," Hobart Rogers states that he believes that blood chloride estimations are practically valueless in nephritis, owing to the coincident retention of water by the kidney which is deficient in chloride excretory power. He has observed that the Folin Wu method for blood creatinin estimations give lower values than the Myers Lough method when applied to the same bloods.

Others have reported similar observations with new blood sugar methods. Rogers feels that it is necessary to know the method by which a given result was obtained in order to properly interpret it and that clinicians must build up a new set of clinical data whenever a new method is adopted.

Dr. Barbera reported twelve cases of cervical ribs reviewing the embryology and symptomatology and pointing out the fact that they often closely simulate neuritis, arthritis, myositis and aneurism. Eighty-five per cent of these anomalies occur in women. Surgery is indicated in a small per cent, being necessary in only one of his cases. The doctor warns against too hopeful a prognosis when surgery is resorted to. The non-surgical treatment, which consists of exercises and braces, was outlined.

The interesting discussions of these papers were participated in by A. C. Siefert, Gertrude Moore, O. D. Hamlin, S. A. Jelte and N. A. Cary.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held Saturday evening, June 27, at the offices of Cunningham and Carpenter in Richmond.

Wallace I. Terry was the speaker of the evening. He discussed the various actions of intravenous drugs on the bacteriostatic action in the blood stream and organs. A lively discussion followed and much good resulted therefrom. We wish to have Doctor Terry with us again in the future.

Leopold H. Fraser was elected to membership in our society, a valuable member, and we were delighted to receive him. The members adjourned after the meeting to Marino Grill, where lunch was served. The following members were present:

William A. Rowell, Crockett; Rosa A. Powell, Richmond; C. E. Camp, San Pablo; P. C. Campbell, Richmond; J. P. Breneman, El Cerrito; G. M. Baumgarner, Richmond; Hall Vestal, Richmond; W. E. Cunningham, Richmond; Leopold H. Fraser, Richmond; Denninger Keser, Richmond; F. L. Horne, Crockett; L. St. John Hely, Richmond. Nurses—Elizabeth Redmond, R. N.; Mrs. Nora L. Purviance, R. N.; Mrs. Etta L. Kerfoot, R. N.

FRESNO COUNTY

Fresno County Medical Society (reported by John Montgomery, secretary)—The resignation of T. Floyd Bell as secretary of the County Medical Society was accepted by the Board of Governors, and John Montgomery was appointed to fill the unexpired term of Doctor Bell.

At the monthly luncheon of the society, a traveling bag was presented to Doctor Bell and good wishes were extended to him in his work at the University of California Hospital, where he will do work in obstetrics and gynecology.

At this meeting Father O'Sullivan was the principal speaker. He gave a very interesting description of the organization of Sisters' hospitals in general, and of the plans for the proposed hospital in Fresno. This will be built on a ten-acre site at the corner of Fruit and Floradora avenues. It will be erected by Nuns of the Dominican Order. This hospital, as all other of the 500 Sisters' hospitals in the United States, will be operated as a separate and distinct corporation, all the money received being spent in the operation and improvement of the local hospital. The Sisters comprising the Fresno body will donate their services, thus enabling the hospital to keep costs down within the reach of many who cannot now afford hospital care. All donations given the hospital here will cut down the interest charges and thus enable the hospital to still further lower hospital costs. There will be an open staff of physicians and the hospital will be available to patients of all creeds alike.

The first hospital opened in the new world was opened by a body of Nuns; the City Hospital of New Orleans is operated by such a body; as is also the hospital of Mayo Brothers at Rochester.

There are 500 such hospitals in the United States at present and in them are half of the hospital beds in the country.

By discussion and questions it was brought out that hospital construction costs would amount to about \$3600 per bed, this figure to include all accessory buildings and equipment. It is expected that the local hospital will begin with an initial fifty-bed capacity and increase as the work warrants extension.

Fresno County Hospital has recently graduated eight internes and now has in their places, Doctors Wightman and Paine from Northwestern, Doctors Hazel and Gleason from University of Michigan and Doctors Baldwin, Owens, Nilsson, and Hershey from Loma Linda.

The new unit of the Fresno County General Hospital is nearing completion. This is to comprise the outpatient clinics, the admitting department, emergency dressing rooms, x-ray, and maternity wards.

Doctor Frank Ruff has recently taken charge of the x-ray department of Burnett Sanitarium. Doctor Ruff comes to Fresno from the U. S. Public Health service at Fort Lyon, Colorado.

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—Meeting of Marin County Medical Society was held on June 18 at 8 p. m. at the rooms of the San Rafael Club. The meeting was opened by H. O. Hund, president.

The following members and guests were present: Doctors H. O. Hund, Josephi, Marsten Jr., Masurio, C. W. Clark, L. L. Stanley, R. M. Furlong, W. F. Jones, A. H. May, J. H. Kuser and Harry Spiro, who was invited as a guest.

The order of business was dispensed with so that Doctor Spiro had ample opportunity for his paper. The doctor gave an extremely interesting address on angina pectoris and its various manifestations, after which a general discussion followed.

MENDOCINO COUNTY

Mendocino County Medical Society (reported by P. J. Bowman, secretary)—On June 27, at 7 p. m., there was held a supper, followed by a joint meeting of the Mendocino and Lake County Medical Societies, to which the Sonoma Society was invited as guests, at the Palace Hotel in Ukiah.

President Raymond Babcock presided. The speaker of the evening was Carl Hoag of San Francisco. He presented two very helpful discourses on goiter and fractures of the forearm, each of which was followed by general discussion.

At the end of the regular meeting there was an election of officers of the Mendocino Medical Society for 1925-26. Homer Wolfe of Albion was elected president, and P. J. Bowman, secretary and treasurer.

ORANGE COUNTY

Orange County Medical Association (reported by D. R. Ball, secretary)—The regular monthly meeting was held May 5 at the Orange County Hospital. Thomas S. Blair of Santa Ana read a paper on "The Legitimate and Illegitimate Use of Sedatives, Anodynes and Narcotics." The author drew largely from his experiences as head of the Bureau of Narcotic Enforcement for the State of Pennsylvania, which position he held for many years before coming here. Albert Hoffman of Anaheim read a paper on "Experimental Work on the Etiology of Peptic Ulcer." The writer has just completed an extensive piece of research work in proving the specific bacterial cause of ulcer and his results were reported in the paper. He exhibited a number of specimens showing experimental ulcers produced in guinea pigs during the course of his experiments.

The June meeting consisted in a joint gathering with the Orange County Dental Society at St. Ann's Inn, Santa Ana, the evening of June 2. Some sixty odd members of the two organizations were present. The subject of "Focal Infection" was chosen for common discussion. George Dock of Pasadena presented the medical point of view. Dr. Dock has been one of the pioneer workers in this field and drew largely from his own observations in his able discussion. Charles E. Wonder, D. D. S., of Los Angeles, presented the dental aspect. He emphasized the point that many devitalized teeth, which do not show abscesses in the x-rays, may be foci of virulent infection and should be removed if other more evident places of absorption are not found. A spirited general discussion followed from the members. The meeting was, on the whole, one of the most enjoyable and profitable that the society has had for some time.

The Santa Ana Clinical Society met at Ketner's Cafe the evening of May 22. The speaker of the evening was Dr. Maynard, pathologist at the Los Angeles General Hospital. He presented a review of the question of bubonic plague in general and then went on to a description of the pneumonic outbreak of some months ago in Los Angeles. Charts were shown of the epidemiology of the outbreak tracing the spread from case to case. In conclusion a series of lantern slides, showing the different pathological features of the disease, was shown. The talk was considered most worth while by all present.

A recent development of much importance, both to the

community and to the local profession, is the organization of a visiting staff at the Orange County Hospital. This movement has been under discussion for some time and has now taken concrete form. The staff for the present hospital year includes the following members: Surgery, J. M. Burlew, D. C. Cowles and H. A. Johnston; medicine, J. L. Maroon and D. R. Ball; pediatrics, Joseph Robinson, W. S. Wallace and R. P. Yeagle; obstetrics and gynecology, J. H. Lang, S. A. Marsden and Bessica Raiche; otorhinolaryngology, C. H. Brooks, M. H. Heldman and H. D. Newkirk; neurology, F. E. Coulter and R. A. Cushman; urology and dermatology, C. R. Lane. The staff is organized as follows: President, Harry E. Zaizer, superintendent of the hospital; vice-president, H. D. Newkirk, and secretary, C. R. Lane. A schedule of attendance for ward and clinic duty has been worked out and the full staff holds a scientific meeting the third Thursday of each month.

One new member has been taken into the society in the person of William C. Bruff of Anaheim.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reporter by Bert S. Thomas, secretary)—The June meeting of the local society was devoted to a "Clinical Evening." It was held in the new auditorium at the Sacramento Community Hospital. Those in attendance included Doctors Nahl, Scatena, Yates, Babcock, Jones, Thomas, Gundrum, Beach, Thom, Stern, Dillon, Hale, Dunlap, Soutar, Snyder, Farrell, Brown, Atkinson, Beattie, Lindsay, Cress, Lubben, Schoff, Murphy, Wilder, Turner, Lipp, Klick, Parkinson, Drysdale and Wise.

A word about the attendance before turning to the more interesting program of the evening. On May 18, 1925, California Medical Association adopted the following resolution:

"Resolved, By the Board of Councilors of the California Medical Association that the attention of the members of the constituent County units, who, at the same time, are members of attending hospital staffs in their respective communities be called to the importance of not overlapping or interfering with the proper scientific activities of both these highly important expressions of medical activity and development.

The scientific programs of the attending staffs should concern themselves especially with the diseases and injuries of patients in such hospitals. The attending staff scientific programs should not take the semi-abstract or literary trend that has long been and must necessarily continue to be a natural part of the scientific programs of County Medical Units.

Our County medical societies are the constituent units of organized medicine in our state, and the development of organized medicine is absolutely essential to the protection and further growth of both the scientific and material interests of medicine in California.

Your Board of Councilors presents these suggestions for the consideration of program committees of attending staffs so that these basic facts, which are of so great importance to County Societies and attending staffs, may be constantly kept in mind."

It seems that a good number of members should have their attention particularly called to this resolution as there is no doubt that certain members of our local hospital staffs are neglecting their most important medical constituent unit, probably due to the fact that a considerable portion of their time is taken up with their respective staff meeting. By examining the attendance of both the Sisters' Hospital and Sutter Hospital staff meetings, it was found that a number who have faithfully attended these meetings each month, have attended our otherwise well-attended meetings either not at all, or but once, so far, this year. We believe that the resolution adopted by the State is a very wise one, and wish to call your particular attention to it.

To the meeting itself: The minutes of the May meeting were read and approved. In the report of the board of directors, it was announced that the September meeting will be in the hands of the roentgenologists, and that the other two scientific meetings of the year would probably be devoted to a Surgical Symposium and a Pediatric one.

It was suggested that all members take note of the

fact that the new A. M. A. emblem is now available, and that its use will eliminate the present trouble of permitting practically anybody to take advantage of the parking privileges, now kindly granted by the city to all duly authorized medical men. This emblem has been copyrighted by the A. M. A., and may only be obtained with its registered number through their office. Just as soon as the members are able to obtain their emblem, the police will be notified of its significance.

Secretary reported that Mervyn F. Frandy had transferred from the Santa Barbara Society to the local one. Gundrum moved and Nahl seconded that the annual banquet deficit be paid from the treasury.

Program of the Evening—Leo P. Bell presented three cases of "Banti's Disease." In his remarks, he followed the idea of Rosenow, that the disease is caused by a streptococcus admitted originally through the respiratory tract. The spleen, being a lymph gland, is a filter, and, through this filtration, becomes infected. The primary stage of the disease is a thrombo-phlebitis of the capillaries. The disease, as originally described, was really what we now recognize as the third stage of the disease; the first stage being the pre-acitic stage, without gastric hemorrhage; the second stage is that when gastric hemorrhages supervene, where anemia becomes apparent and leukopenia is present; the third stage, Banti described. Here we have ascites, greatly enlarged spleen, with destruction and regeneration of liver tissue. Bell opposes operation in the first stage. At this time, removal of infectious foci and transfusion are used. Since the damage done as found in the second and third stage is irreparable, since the spleen is no longer acting as a filter but is merely accumulating toxins primarily directed at liver destruction, and, since the pathology is one of fibrosis and endothelial proliferation, the spleen should be removed in these two later stages. Bell sees no reason for less than 100 per cent recoveries after the immediate operative mortality is passed.

In the discussion, Dunlap briefly discussed two of his recent cases; he also asked as to the ground for believing the disease to be one of streptococcus origin, quoting Monihan, who had often declared that if such a case could be traced to a foci of infection, then the disease was not Banti's. Thomas enquired about the relative proportion of permanent kidney damage done in these cases, the question coming from the fact that in a recent case requiring splenectomy, there had been a massive amount of albumen found in the urine at the time of operation; six weeks post-operative there was no trace of albumen to be found.

In closing, Bell suggested that the idea of streptococcus as the causative factor in the disease, was a very recent one. He suggested that the albumen found in these cases was usually due to a nephrosis.

Schoff presented a patient with leprosy. Cigar-shaped bundles of the bacillus were obtained from the nasal septum by the thousands by Snyder.

Scatena presented a rather advanced case of Hodgkins' Disease. He called attention to the fact that Yates and Bunting have regularly recovered a micro-organism in these cases, but they have been unable to establish the cause by completing Koch's cycle as proof. In discussing this case, Gundrum classified Hodgkin's Disease as one group of what he was pleased to term "Lymphocytomata."

Beach presented two cases of peri-nephritic abscess, one of which was of a primary type, and one of the secondary type. Hale had seen the last case four years ago, and had the pyelograms taken at that time to compare with the present ones.

Gundrum presented a chart of a severe diabetic, six months' pregnant, and with a bi-lateral pyelitis. It was most interesting from the standpoint of sugar tolerance, the use of insulin throughout, and the variation in the whole picture during an intercurrent staphylococcus aureus blood infection.

Babcock discussed a case presenting a typical Parkinson syndrome in a child.

The meeting adjourned to the banquet table.

Sacramento Society for Medical Improvement (reported by Bert S. Thomas, secretary)—In view of the fact that we have no July or August meetings, I wish to

report various notes of interest that have occurred since our last meeting.

A note was received from the office of the surgeon of the Ninth Corps Area, showing us that there is but one member in good standing in our society on the list of Reserve Medical Officers. This is Major Archibald A. Atkinson. There are four other local physicians on the list. We believe that the men of our society should heed the call that the army is sending out, and suggest that they volunteer their patriotic service to the nation in time of national emergency.

We are happy to welcome Hans Schluter to Sacramento. He comes to us after four years of post-graduate work in obstetrics, with the idea of handling this type of work only. He has not, as yet, affiliated with the state organization, but we feel sure that we can report him as our next new member.

Doctor Titus of Great Falls, Montana, is anticipating entering practice in Sacramento, about August or September.

June B. Harris is reported as having left for home from his trip to England.

Norris R. Jones is the new resident at the Sutter Hospital.

Angus McKinnon comes to us from the San Francisco Hospital as the new resident at the Mater Misericordiae Hospital.

A letter has just been received from W. E. Briggs from Paris. After starting from the Orient, and constantly heading West, the doctor is now well on the last leg of his year's trip around the world. He is expected home in September.

J. W. Crawford is still in Philadelphia, taking post-graduate work in eye, ear, nose and throat.

Oscar Johnson, returning from the American Medical Association gathering, reports a most enthusiastic meeting. His visit to the Massachusetts General Hospital was particularly interesting.

We have to report the loss of a good member. George Sanderson has left Folsom and has entered practice in Stockton.

William Miller has found it necessary to convalesce in Colfax. We wish him a speedy return to our active circle.

Harry R. Baird has returned from a tour of the South.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock, M. D.)—The monthly dinner for June was held by the County Medical Society in the San Diego Hotel on Tuesday, June 9. Business was suspended for a splendid scientific program as follows:

1. J. C. Yates gave a very practical talk on some medico-legal questions upon which the rank and file of our profession should be better informed. The various workings of the Anti-Narcotic Law seemed to have especially called for explanation.

2. C. L. Stealy discussed at some length the technic of the Salivary Urea Test, based upon original work done by himself in his private and hospital practice. While there is a strong appeal to a quick test of this sort which can be done in the office without drawing blood from the patient, Stealy's conclusions were that the discrepancies between this test and the standard blood urea test were so wide as to make the former seem unreliable. The paper was intelligently discussed at some length by R. J. Pickard and E. F. F. Copp. The latter's experience with the test under consideration led him to feel distinctly more favorable toward it than the other speakers.

3. Bronchiectasis, a symposium presenting the various aspects of the subject. L. H. Redelings outlined the clinical diagnosis with emphasis on the desirability of an early diagnosis being made; H. A. Thompson presented a clear summary of the pathology of the subject. Elliott presented a radiography of the subject with some excellent x-ray films, some of which showed the value of surgery in this condition. Dr. Elliott also discussed the value of laryngeal injection of lipoiodol in outlining the pathology of the subject by x-ray. C. M. Fox closed the symposium with a comprehensive description of the

various surgical methods used in the treatment of this troublesome bit of pathology.

The following physicians were recently elected to full membership in the society: A. M. Muhl, Alice Huff Crandall, W. F. McColl, A. B. Smith and W. T. Dunn. Doctors Albert Martin, H. M. Fine, L. J. Bernard and E. U. Reed were elected to associate membership. Charlotte Baker, one of our honored members, was recommended for the permanent fellowship in the A. M. A., in accordance with the provisions for such fellowship in the latter's constitution.

J. W. Sherrill, director of the Scripps' Metabolic Clinic, has returned from an extended trip in the East, visiting his former associate, Dr. Frederick M. Allen of Morristown, New Jersey. While away, Doctor Sherrill delivered papers at the California Medical Association in session at Yosemite National Park, as well as at the A. M. A. in session at Atlantic City.

The following members of the local profession have returned from the East after visiting the A. M. A. and various other clinics: Grace M. Kimball, J. D. Hartley, Robert Pollock, William Ruoff, Arthur Wegeforth and George B. Worthington.

E. F. F. Copp of the Scripps' Metabolic Clinic is now in Toronto, Canada, where he was formerly associated with Doctor Banting. On this visit, Doctor Copp read papers at the California Medical Association at Yosemite Park and at the Canadian Medical Association at Regina, Canada. Copp has already made for himself a warm spot in the hearts of the local medical profession.

National Defense Day was recognized on July 4 by a liberal registration on the part of the medical men, dentists and nurses of San Diego, many of whom were in line in the splendid military parade during the forenoon. Our national patriotism is kept warm through the untiring enthusiasm of Lieut. Col. Alfred E. Banks, in charge of Evacuation No. 90 of San Diego.

Already the program committee is at work getting out some attractive papers for the fall, as the society resumes its session in September.

SAN FRANCISCO COUNTY

Franklin Hospital Staff (reported by Ewald Angerman, secretary)—A staff meeting of the Franklin Hospital Clinical Society was held at the hospital May 4, 1925, at 8:30, Frank R. Dray presiding.

At this meeting, Doctor Shiels urged more support for the County Medical Society, which was concurred in by all those present.

The paper of the evening was presented by Conrad Weil, choosing for his subject, "Surgical Treatment of Lung Tuberculosis at the Clinic in Munich." Doctor Weil, who recently returned from abroad, gave a very interesting and instructive outline of his experiences in Europe.

CHANGES IN MEMBERSHIP

New Members—Los Angeles County—Howard R. Cooder, Ruth J. Temple, G. J. Torell.

Sacramento County—Royal de R. Baronides, John West Wilson.

Glendale County—Harold J. Cooper.

San Diego County—William T. Dunn, William F. McColl.

Santa Monica County—Charles E. Rooney.

Long Beach County—Francis B. Settle.

Transferred—Clement H. Arnold, from Santa Clara County to San Francisco County; S. S. Kalman, from Alameda County to Siskiyou County; Mervyn F. Frandy, from Santa Barbara County to Sacramento County; Lolita F. Flewelling, from Orange County to Alameda County; Charles A. Love, from San Luis Obispo County to San Bernardino County.

Deaths—Bluhm, George Irving. Died at San Francisco, June 20, 1925, age 57. Graduate of School of Medicine, University of Illinois, 1894. Licensed in California in 1901. Doctor Bluhm was a member of the San Francisco County Medical Society, the California Medical

Association and a Fellow of the American Medical Association.

Endicott, Edwin Eugene. Died at Jackson, June 27, 1925, age 51. Graduate of the Kentucky School of Medicine, Louisville, 1894, and licensed in California the same year. Doctor Endicott was a member of the San Joaquin County Medical Society, the California Medical Association and a Fellow of the American Medical Association.

Freeman, William. Died at Fullerton, June 29, 1925, age 84. Graduate of the Indiana Medical College, Indianapolis, 1877. Licensed in California in 1895. Doctor Freeman was an honorary member of the Orange County Medical Society, the California Medical Association and the American Medical Association.

Associate Editor for Utah

VACATION TIME

All work and no play is said to make Jack a dull boy. And why not? If all life phenomena partake of the nature of electro-magnetic manifestations—if the cell, be it brain or muscle or gland, be but a minute electro-magnetic cell in its primal nature—a tiny storage battery as it were—then why should too much, too steady, too continuous use of one such series of cells not gradually bring about a state of exhaustion which shall make us dull indeed? Actually we burn our batteries out.

In this sense change of endeavor, of application or of scene is synonymous with rest. And certainly the doctor needs rest whether his patients realize the fact or not. Because the doctor is human—regardless again of what his patients say or think, and the doctor plays a pretty steady shift. In reality it's twenty-four hours long, unless the particular medico who proves the exception has arrived at a point where he may leave much to his assistants and thereby slip off now and then for a seance with a golf ball as a form of rest. And not only is it twenty-four hours, but it's seven days in a week. In addition, the doctor does not live his own life; he lives many lives. That is, the interests, the welfare of many lives are constantly with him. He takes his cases to bed with him—figuratively, of course. Going back to an electrical comparison, the doctor's brain cells are always "cut in"—always at work. And this way lies brain fag.

Consequently the doctor needs a vacation just as much as any of his patients—all of whom are ready to declare that they need and deserve a rest, because—brain fag means less effective work. Less effective work is apt to mean disaster to both the patient through lack of desired result and to the doctor through loss of prestige, failure to deliver and, therefore, added mental stress.

But vacation—change of scene, a meeting with other and possibly fresher minds—rest, means a return to routine with a freshened zest. In this sense vacation for the medical man is an actual investment for the benefit of both the patient and the doctor himself. There is a very potent source of recuperation in a golf ball or a fishing rod if properly used, even though the nineteenth hole is not as

popular as it was before the eighteenth amendment got in its work.

THIS MONKEY BUSINESS

As we write they are "Hangin' Danny Deever in th' Mornin'." In other words they are trying John Scopes. The little town of Dayton, Tennessee, is selling soft drink stand concessions about the courthouse—the last issue of Judge has printed a cartoon of William Jennings Bryan with a monkey perched upon his head, plucking at his few remaining hairs, and captioned "He loves me, He loves me—not," and the Great Commoner himself has stood on a hill outside of Dayton and preached a sort of sermon on the mount.

Verily, yea verily, the antics accompanying the Scopes trial might almost inspire one with a feeling that the theory of evolution—or rather of anthropoidal descent from the monkey—were well founded were it not for the deeper meaning masking back of its more farcical face.

Whether man be descended or *ascended* from the monkey tribe, or whether they are but branches of a common trunk, we do not undertake to state. Certainly man himself is guilty of much which makes the possibility seem not so far fetched. But God is God and certainly as the Creator of the Universe not to be proved or disproved by the trial of a high-school professor twenty-four years of age.

The pitiful part of the thing to our minds is, that there should in reality be any quarrel between science and religion—or any man or sect of men today so narrow-minded as to feel that there is any conflict between mankind and his God. Science recognizes God—his works. And the latter should speak to man of His verity in themselves. Any other assumption than that of an Intelligent Creative Power back of the Universe of which our Earth is a part, is an insult to intelligence. And the Scopes trial will settle nothing except the two points as to whether John Scopes is convicted, and the State of Tennessee has a right to pass a law telling its people what to say and what to think.

But the great danger in the episode is really to ourselves. Too much are we "monkeying" with law, until we are threatened with a very plague of laws. We are told what not to do to such an extent that the very inhibition becomes the cause of law breaking, through the average man's resentment of the attempted infringement of the God-given rights of personal choice. What the race needs today in this country is a greater recognition of natural law, and a fewer and saner number of man-made laws. Forbidding a man to drink won't stop his drinking. Q. E. D., as the geometers put it, "that has been proved." Forbidding a man to think, we feel won't stop his thinking. Commanding a man to believe will not greatly bolster his faith. Thought and faith are both things EVOLVED, and God alone could have made a man out of either a bit of clay or a monkey. For the rest, this monkey business is just—monkey business after all.

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—A special meeting of the Salt Lake County Medical Society was held at the Com-

mercial Club, Salt Lake City, June 18. Meeting was called to order at 8:10 p. m. by President John Z. Brown. Fifty-three members and three visitors were present.

The speaker of the evening was James F. Cooper, Medical Director, Research Department of the American Birth Control League, Inc., New York City. He talked of the aims, principles and policies of the league and discussed in detail the results obtained by investigation in the Contraceptive Clinic in New York City.

Utah Notes (reported by J. U. Giesy, associate editor for Utah)—Doctor H. P. Kirtley has left the city by motor for a trip to Portland, Seattle and Vancouver.

Doctor Foster Curtis has returned from a trip of over four thousand miles by motor, including in his itinerary Bryce's Canyon, Los Angeles, San Francisco, and Portland.

Doctor E. M. Neher is back from a trip by rail and boat to Alaska.

All these things hit in well with our editorial on vacations. And we plead the sentiment there expressed as excuse for the brevity of notes for the current month. Anyway, it's too hot to work or write and the asphalt is becoming a quaking morass in the middle of the street. Utah is experiencing the hottest wave in the history of the local weather bureau and we feel like taking our own advice about a vacation. Still, with seven beautiful canyons within easy motor distance from the heart of the city, why should anybody complain of the heat?

The 1925 Session—The following changes in information about the U. M. A. meeting in September should be noted.

Doctor Engman, through causes of unpreventable nature, will not be present as scheduled.

Wallace I. Terry (Surgery) and Frank W. Lynch (Gynecology), both of the University of California, will be present however. In this we have been fortunate.

Walter C. Alvarez, who will be present, is Asst. Professor of Research Medicine, the Medical School of the University of California, and not Professor as was erroneously published last month.

John Sundwall of the University of Michigan will, it is now hoped, be the chief speaker at the public meeting to be held during the U. M. A. session.

It is the plan of Doctor Goeltz of our program committee to drive to Pocatello, Idaho, where many of our guests are to be on the program of the Idaho State meeting, and bring these gentlemen back with him in cars, with a dinner en route, so timing the trip as to arrive here Sunday night before the opening of the Utah meeting.

Flaccid Paraplegia—Two cases of flaccid paraplegia are reported by Edward Livingston Hunt and Leon H. Cornwall, New York (Journal A. M. A.). In the first case the postmortem examination disclosed a thrombosis of the abdominal aorta beginning about 5 cm. above the bifurcation of the common iliacs and extending downward into the femoral on the right and just to the femoral on the left. The thrombus was reddish white, firm and well organized. From gross examination it appeared to obstruct completely the lumen of the aorta, both common iliacs and their external and internal branches. From the gross appearance of the thrombosed portion of the aorta and its branches, it appeared that the occlusion was complete. But microscopic examination showed that there were small channels between the margin of the thrombus and the intima of the aorta containing blood. The dorsalis pedis and its branches also contained a moderate amount of blood. The second case represents a case of extensive softening and degeneration of the spinal cord following an extradural hemorrhage. The hemorrhage induced mechanically a thrombosis of the vessels that furnish the blood supply to the cord, the resultant pathologic change being one of ischemic softening. As would be expected from the extensive degeneration of the gray cornua and white columns of the cord, the clinical picture was that of complete flaccid paralysis, complete anesthesia to all types of sensation below the level of the lesion, bladder and rectal incontinence, and atrophy of the musculature of the lower extremities.

CORRESPONDENCE

POPE TRAVELOGUE

Leslie Simson's Camp,
Tanganyika, May 25, 1925.

My dear Dr. Musgrave:

It is about a month since I wrote you last and many events have transpired since that date.

We have kept up our wild career of lion hunting and have the skins of twenty-five of these mighty beasts hanging outside our storeroom. Eight lions we have killed entirely with our bows and arrows, and our experiences have been varied and exciting. We have stood fourteen charges, stopping most of their rushes at three to five yards. Our shooting distances with the bow for these beasts extends from forty to eighty-five yards.

Two lionesses have charged our motor car while we were rounding them up. In one of these whirlwind stunts I was riding on the running board, ready to hop off and shoot with my bow when a sudden turn of the lioness and a corresponding swerve of the car nearly threw me off into her jaws. It seemed funny at the time. I held on by one finger and we had to dispatch this dangerous lady with a rifle. She tried to climb in the front seat.

We have a small number of other animals added to our list such as hyaenas, jackals, leopards, cheetas, wildebeasts, Tommies, elands, foxes, badgers and zebras. Besides a large number of regular camp meat secured with the gun.

But so long as one hears the low menacing grunt of a lion on the velt and the thunderlike roar of their team work at night as they round up their kills; so long as one can go out as we did this morning and see fourteen of these lordly beasts file slowly out of the donga where they have fed upon fresh meat, this long will one's muscles tighten, the blood pressure rise and one feels the urge to "go and get 'em"! And we do.

We did not attack these fourteen, but ran them, cut out two large males from the bunch and brought them to bay out on the plains. There we fought it out to a finish.

Incidental to all this feverish diversion, I have been laid low with quotidian malaria, and now I am feeding upon quinine. We have also the tsetse fly at our very doors, but they are reported to be uninfected with trypanosomes. The anopheles also were reported to be "not loaded"—but you know how that sort of a gun goes off!

I've been keeping tab on the livers of all our animals for Doctor Mentzer of the Mayo Clinic and have done the autopsies of seventy-five individuals and made drawings and measurements of the gall ducts of fifteen different species.

The weather continues mild, the evenings chilly with warm afternoons and occasional showers. It is much like California in Tanganyika, so we contemplate staying here in our present camp for two or three months, later going to the great volcanic crater of Ngorogoro.

We are surrounded by immense quantities of game though it is not all accessible for bow shooting. Our nearest native village is Ikoma, a district of scattered huts, numbering in all a thousand or so inhabitants. It is, of course, the big metropolis of these parts. It has no postoffice, no stores, no roads, no white men, but just as important to the noble tribe of Wakoma as Los Angeles is to the world at large. It has its own heated existence and, doubtless, to some the world revolves about Ikoma. I take it, therefore, that you will be deeply interested in the little bits of gossip that we pick up from this center of learning.

I send an alleged clipping from the principal newspaper of Ikoma:

"The Ikoma Garbage Can,"

Emptied on very rare occasions.

The latest news from the royal household is to the effect that His Royal Highness—Mtone, Sultan of the illustrious Wakomas—is still in excellent health,

though somewhat somnolent, owing to the solicitous care of his four wives and the unlimited amount of sour beer which he consumes.

It is reported that at the nearby camp of Bwana Simson there are three Volstead Americans. It is devoutly to be hoped that no modern social improvements will be introduced to our glorious land through their influence.

The Crowned Prince, Masheke, has recently returned from Bwana Simson's Camp, accompanied by his beebe number three, mother of his alleged latest royal offspring. They bear rich presents from the Americans, to-wit one gaudy skull cap, valued at 25 cents, and one red, white and blue handled Boy Scout knife. Masheke was ever the child of fortune!

Dame Scandal has it that the pretty beebe of Maridi has left his bed and board and now resides at the banda of Bwana Simson's brave gun-bearer, Kazimoto. Maridi has sharpened his pangs and taken his longest spear from the doorway. Nothing will satisfy the honor of our most worthy townsman but the blood of Kazimoto, or the payment of five shillings.

Latest advices—Kazimoto has paid a prince's ransom for his folly. He disgorged the sum of five shillings into the coffers of Mavidi, who tied the wad up in the corner of his shuka or loin cloth, and his honor is vindicated. He has now taken service with the great Bwana Simson as porter at 10 cents a day. Kazimoto and his new beebe have started on their honeymoon to Nairobi, 240 miles by the trail. The walking is excellent this time of the year.

NOTICE IS HEREBY GIVEN OF THE GREAT COMING CEREMONY, THE FESTIVAL OF CIRCUMCISION. All youths between the ages of thirteen and fourteen are hereby commanded to appear at the banda of the medicine man at the appearance of the full moon.

Cheer up, boys, the fundi is the possessor of a very long sharp knife, the music will be grand. This is the one big event of your young life. Reserve seats for ladies as per usual will be two handfuls of ground meal. Come one, come all! Register your bets with the gatekeeper and leave your spears outside!

Tembone, the mighty hunter of the Wakomas, has recently returned from Bwana Simson's camp where he presented the Great Bwana with a pumpkin and half a dozen yams, asking modestly in return that the Bwana shoot him two zebra with his punduke.

It is reported that our fellow townsman was given a shilling and a toy balloon in payment. Tembone enjoys these little walks of seventy miles, and after all his toto packed the vegetables.

FOR SALE! CHEAP!

One loin cloth, three yards mericani, slightly used, 5 years' wear, and a coil copper wire ankle bracelet in exchange for one young wife, must have amiable disposition. Apply to Dolo, the flute player.

Feeling that I've given you all the news that's fit to print, I draw this sad epistle to a close.

I am as ever,

Very cordially yours,

SAXTON POPE.

Mercury Rubs—It has been pretty clearly demonstrated that the mercury that is rubbed into the skin is absorbed from the sebaceous glands and hair follicles, and to some extent from the sweat glands. What is left on the skin after the rubbing is over is of no service, and cleanliness suggests that it be thoroughly washed off with benzene or other solvent.

What the physician, convinced of the practicability of mercurial medication, by way of the skin, is particularly interested in is an ointment that can be used with some degree of scientific exactness, and one that does not advertise the patient's misfortune to his acquaintances. Parke, Davis & Co. are offering little cakes or blocks of cocoa butter, containing metallic mercury, which they call Mercurettes, and which the patient can conveniently carry with him, on occasion subdividing them into halves or quarters for use. Each Mercurette contains fifty grains of mercury, uniformly distributed throughout the mass. See advertisement in this issue.

Analysis of
KLIM
 POWDERED WHOLE MILK

	<i>Dry</i>	<i>Liquid *</i>
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

**KLIM is not merely
a milk for infants**

KLIM is whole milk with 1½% instead of 87½% moisture. By the addition of water it is restored to liquid milk with the normal caloric value and analysis.

The flavor of fresh milk is well preserved in KLIM.

The full nutritive value of milk and vitaminic potency are undiminished.

Its increased assimilability makes it an ideal milk for the growing child. The transition from the baby's feeding to the child's ration is merely the removal of the last slight modification.

Its price permits its general use in the home, as a pure milk of known origin, fully guaranteed by the largest manufacturer of powdered or dried milk in the world.

Castle Uses Bronze for Your Greater Protection

Bronze adds indefinitely to the life of your instrument sterilizer in the surgery. It is a seamless, solderless, rivetless casting, and so is a safeguard against trouble and repair charges, should the sterilizer be forgotten.

Rounded corners facilitate cleaning. The heating coil of the steam model is cast right into the metal of the bottom, leaving the bottom smooth and free of residue-catching pockets. The famous Castle simultaneous cover and tray lift is included—a foot lever operates it.

New Utensil Sterilizer

The new mechanical pump is an advantage to the *utensil* sterilizer in addition to the solid bronze cast bottom, sloped for easy drainage. This pump operates efficiently and smoothly by foot and obviates complicated mechanism.

CASTLE

Complete line of Physicians', Dental, Hospital and Bacteriological Sterilizers

Castle sterilization is
based on proven authority

Cerebral Vasculature—Fifteen brains were prepared and studied by Temple Fay, Philadelphia (Journal A. M. A., June 6, 1925). Five were injected after removal with metallic mercury. Ten were injected in situ with barium sulphate, and later removed for study. The studies seem to indicate that communications are numerous between the various zones of vascular supply, and that these communications are of considerable size, available for collateral circulation. In cases of thrombosis of one of the cortical cerebral trunks, lowering the head, raising arterial pressure with the application of heat to the overlying scalp, may offer some added chance of improvement or recovery if the patient is seen early, and if the thrombosing process has not involved the anastomotic branches. Some degree of anastomosis has been evident clinically, frequently seen in the recovery of temporary loss of function, and has usually been explained on the re-establishment of the arterial supply through the thrombosed vessel. The extent of end arteries in the brain as shown by these injections varies in different preparations. A wide range of factors may influence these findings, such as degenerative changes in the vessels themselves, postmortem clotting, and uneven injection by the opaque fluid. It seems evident, however, that the subcortical regions are supplied by end arteries. With few exceptions only, anastomotic branches can be traced in the stereoscope; these are not constant in each specimen. A more intensive study of these branches is now being undertaken, particularly in the fields of each arterial supply, the points of fusion between the three main systems being characterized by anastomotic branches. It seemed, on study of the three large arterial supplies to the cortex, that the frontal lobe supplied by the anterior cerebral differed considerably from the remaining two arterial distributions. This was most marked in the appearance of large, swinglike loops dropping down from the cortex, probably following the convolutions and radiating toward a center near the anterior horn of the lateral ventricle. The circuitous course taken by the anterior cerebral artery to reach its areas of distribution differs in that seen from the middle and

posterior cerebral arteries, which show few loops of this character and tend to run more directly to their source of distribution on the cortex. Perhaps the inference could be drawn that the frontal lobe has developed more recently than the phylogenetic plan of the arterial system produced for its supply, and consequently the more recent demands on this vessel have given rise to the complexities throughout its distribution.

The Female Sex Hormone and Gestational Gland—Robert T. Frank and R. G. Gustavson, Denver (Journal A. M. A., June 6, 1925), summarize their most important conclusions thus: Each sex cycle is preparatory to gestation, the normal sex cycle being the fertile one that leads uninterruptedly to parturition and lactation. An abortive cycle occurs when pregnancy fails to develop. Soon after ovulation the anabolic phase ceases, a catabolic period succeeding it. In most forms the catabolic period is involutionary. In the primates this period is destructive (menstruation). The endocrine factors producing the cyclic changes are successively supplied by the follicle, corpus luteum and placenta. To emphasize this continuity, the authors propose the name of the gestational gland for this triad (follicle, corpus luteum and placenta). By substitution (subcutaneous injection) with lipoid extracts of these glands (follicle fluid, corpus luteum, placenta) they have obtained: In female castrates or in immature animals alike: (a) premature sex development (pubertas praecox); (b) hyperplasia of the tubular system and mammae, especially marked in rabbits. In castrates: (c) in rats, vaginal spreads characteristic of estrus, together with hyperplasia of the duct system; (d) in rats, treated with potent extracts, typical estrual contractions of the uterus suspended in Locke's fluid. The active substance has been sufficiently concentrated to produce physiologic results in a total dosage of 2.25 mg. (0.00225 gm.). The sex hormone is a specific substance elaborated by the gestational gland, taken up by the lymph and blood stream and selectively utilized only by Muller's tract and the mammary glands. The chemistry of the sex hormone is not fully determined.

Fruits for Non Sugar Patients

Fruits may now be prescribed for non-sugar diets, even when fresh fruits are not available.

Nutradiet canned fruits are the best quality fruits—the famous S & W standard of quality—packed *without* syrup.

Instead of sugar, Nutradiet fruits are canned in sterile water or natural juice. And a part of the natural sugar passes into the water after canning, leaving Nutradiet fruits with even less sugar than the fresh fruit.

Chemical analyses of Nutradiet fruits will be sent gladly on request. Also list of grocers where Nutradiet fruits may be purchased.

[[Nutradiet salt-free vegetables
are packed without salt or sugar.]]

Wellsworth Professional Unit for Oculists

Here is the only complete refracting unit which is attached to the chair. It combines economy of space with convenience for the refractionist and comfort for the patient. It requires less space to house and operate than any other unit. The adjustable back, seat, headrest and arms give the patient utmost comfort.

The instrument support permits the use of each instrument independently. Each instrument swings before the patient in regular routine.

Equipped with scientifically precise Wellsworth-DeZeng diagnostic instruments, it is the most accurate and practical unit obtainable. The scientific appearance favorably impresses and increases your clientele.

Whole Grain Wheat

Inquiries by some doctors and by numerous other persons of the Better Health Service seems to indicate that the propaganda of the Whole Wheat Co. is pleasing—to them. The guiding force behind the Whole Grain Wheat Company, according to the Investigating Department of the A. M. A. (Journal A. M. A.), seems to rest in its president, C. H. Woodward, whose name appears extensively in the advertising. The company's advertising methods are ingenious and many. In addition to advertisements in the ordinary channels, newspapers, etc., the Whole Grain Wheat concern publishes a number of booklets and pamphlets, and gets out a monthly house organ, called *The Motive*, which has C. H. Woodward for its editor and publisher and chief contributor. Also the concern, apparently, organizes so-called "food clinics" in various towns and has as a subsidiary advertising organization the high-sounding "American Educational Food Council." This "Council," appears to be a mere "paper" organization.

Woodward argues that the cure for all disease is Whole Grain Wheat because it is *not* denatured, and will make up the deficiencies of the denatured food on which a crazy world is feeding. We are told that Whole Grain Wheat has cured such serious diseases as cancer, tuberculosis, Bright's disease, diabetes and colitis, as well as such conditions as "catarrh," constipation, asthma, bed-wetting in children, etc. So much for the exploitation methods of the Whole Grain Wheat Company. As to the product itself, it is, apparently, nothing more than whole grain wheat, partly cooked.

Physicians & Surgeons Institute of PHYSIO-THERAPY

Announcing Summer Courses of Instruction in Physiotherapy

Physicians, graduates in Medicine only. Class A requirements. August 10 to October 10. Short, intensive, clinical courses.

Instruction will cover technique, indications and contra-indications for the use of each modality in the auxiliary treatment of disease and injury.

The course is adapted to each physician's individual needs in regard to the subject matter taken up, including the length of the course. For further particulars apply in writing.

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for assimilation with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the direction of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT.

The Management of an Infant's Diet

Summer Diarrhea

The following formula is submitted as a means of preparing suitable nourishment in intestinal disturbances of infants usually referred to as summer diarrhea:

Mellin's Food
Water (boiled, then cooled)

4 level tablespoonfuls
16 fluid ounces

This mixture contains proteins, carbohydrates and mineral salts in a form readily digestible and available for immediate assimilation.

The need for protein is well understood as is also the value of mineral salts, which play such an important part in all metabolic processes. Carbohydrates are a real necessity, for life cannot be long sustained on a carbohydrate-free diet. It should also be stated that the predominating carbohydrate in the above food mixture is maltose—which is particularly suitable in conditions where rapid assimilation is an outstanding factor.

Above all is the satisfactory result from the use of this suggested nourishment, which is well supported by clinical evidence.

Mellin's Food Co., 177 State Street Boston, Mass.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

The Crippled Hand and Arm. By Carl Beck. 243 pages. Illustrated. Philadelphia and London: J. B. Lippincott Company. 1925.

This book fills a real demand for a book on the hand, inasmuch as it describes and well illustrates many forms of disability of this member. The chapters deal with the elementary anatomy, function congenital deformities, crippling by injuries, mutilations, burns and disease, disturbances of the arm crippling the hand, and technic.

The reconstructive part, of which there is considerable, is disappointing in character and is of a period at least ten years previous. No use was made of the tubular pedicle skin-flap. From this and from the apparent disregard of the cosmetic appearance, very disfiguring scars resulted, which can not be approved of in modern reconstructive surgery. Nor can we sanction fascial tubes about nerve sutures or the bridging tendons in fingers by silk; nor the making of median longitudinal incisions in hands or fingers, as pictured on the frontispiece and other illustrations of this book.

Aside from the reconstructive work, the book has an instructive and extensive description of crippled hands and illustrates them with a large series of photographs. It also describes well the treatment of webs of fingers and describes a new operation of transplanting a toe nail on a finger.

Personal Hygiene Applied. By Jesse F. Williams, M. D. for sale by advertisers in this issue. Courtesy copy supplied by the publishers, W. B. Saunders Company. Price \$2.50.

A book which, according to the preface, is designed for the use of "teachers and students," and we might add obviously for serious-minded college students. It is a very good book, made up of a surprising assortment of information, essential, in the author's opinion, to "improve the quality of human life." It takes quite a liberal and unusually versatile mind to include much of the contents

of the book under a title of hygiene. While most of the statements made—but not all by any means—will be quite generally accepted, many of them, no doubt, will receive the challenge always invited by dogmatic statements about matters of controversy. The book is about as readable as Gray's Anatomy.

The Life of Sir William Osler (two volumes). By Harvey Cushing. For sale by advertisers in this issue, price \$12.50.

A book worthy of its peerless subject which is equivalent to saying that it is the best biography since that of Pasteur. It is as fascinatingly interesting as fiction and is a stimulating and inspirational influence that every one who can read should have. Osler will, unquestionably, be portrayed in history as the ideal physician that his friends and students considered him during his life. But he also was a great citizen and people who think, from all walks of life, will find much that is helpful and more that is charming in this remarkable story of the life of a remarkable man.

Diseases of Children for Nurses. By Robert S. McCombs, M. D. Price \$3. For sale by all book dealers listed in the advertising pages of this issue.

This book appears to be an attempt to write down, as it were, a textbook of diseases of children to suit the intelligence of students of nursing. Like so many similar attempts it fails to make interesting reading. A careful, intelligent examination of many of the medical books for nurses explains in part why student nurses often feel sleepy in class. The book under review appears to us to be an average one of its class. It quite frankly is an exposition of practices and teachings of one hospital. This, if nothing else, would limit the distribution of the book. Many, and we believe the majority of physicians and schools of nursing, will challenge several of the author's statements and question the advisability of others. For example, even at this date this book states a silver solution MAY be placed in the eyes of the newborn "in cases where there has been a pre-existing vaginal discharge." The law in this state and elsewhere requires—and rightly—that this service be rendered to every newborn baby.

Gynecology, Medical and Surgical. By P. Brooke Bland. 1257 pages. Illustrated. Review copy by courtesy of the publishers, F. A. Davis Company. For sale by our advertisers. Price \$11.

Bland offers a textbook on gynecology to the profession,
(Continued on Page 1077)

St. Joseph's Hospital

Buena Vista and Park Hill Aves., San Francisco

Accredited by the American Medical Association, American College of Surgeons. Accredited School of Nursing. Open to all Members of the California Medical Association.

A limited general hospital of 200 beds, owned and operated by the Franciscan Sisters of the Sacred Heart. All classes of patients admitted except those suffering from communicable and mental diseases. This hospital was organized in 1889 and has been in continuous operation since that date. A modern annex was built in 1906. A further extensive building program is now under way.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

CALCREOSE

Intestinal Antisepsis

Attempts at intestinal antisepsis in the treatment of diseases of the intestinal tract that occur commonly during the hot summer months are considered important by many physicians. Creosote is regarded as an intestinal antiseptic of promise. Many physicians prescribe CALCREOSE for that purpose because it is a mixture of approximately equal parts of pure beechwood creosote and calcium oxid and can be taken for a long time without apparently causing any gastro-intestinal disturbance; nor do patients object to its long continued use. Samples of Tablets on Request.

Newark, New Jersey

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game — the coon, fox, coyote — and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

A General Hospital, thoroughly standardized and equipped. Its X-Ray Department, and Laboratories are modern in every respect, and its Training School for Nurses, accredited by the State, offers exceptional opportunities to young women desirous of training for the nursing profession.

Excellent Training School for Nurses

Diphtheria of the Skin—In the case reported by Shields Warren and Lee Sutton, Jr., Boston (Journal A. M. A., June 27, 1925), the skin lesions of varicella afforded portals of entry for the diphtheria bacilli. The patient was 5 years of age. The lesions took on an impetiginous character and became infected with *B. diphtheriae*, probably transferred from the nostrils by scratching. They gradually progressed to extensive hemorrhagic crusted lesions covering about 49 sq. cm. of body surface. Death apparently was due to toxemia, and the necropsy findings were consistent with infection with *B. diphtheriae*. Virulent diphtheria bacilli were recovered from one of the skin lesions, and the histologic picture of the lesion is that of diphtheric ulceration. Sections stained by the Gram-Weigert method showed bacilli morphologically resembling *B. diphtheriae*.

A view of the hospital laundry, showing a "close-up" of the Eight-Roll Flat Work Ironer.

This Prim Press battery does the work of many hand-ironers.

At the Youngstown City Hospital --

If you should pay a visit to the City Hospital of Youngstown, Ohio, you would find there, as in so many representative hospitals throughout the country, a fully equipped hospital laundry, operated with "American" machinery.

In these days, hospital authorities agree that the self-contained laundry means: a ready supply of linens at all times—reduction in the amount of linens necessary to keep in stock, closer supervision, and more direct responsibility for the work performed.

"American" machinery will bring these advantages to you as it has to many others. Our corps of laundry experts will gladly consult with you on any matters of laundry installation or operation.

Write today for complete information.

BALANCING BODY
METABOLISM
with
QUARTZ LIGHT

IT is a well-known fact that faulty or unbalanced metabolism plays an important part in the everyday conditions with which the physician is confronted.

Quartz Light radiations with the ALPINE SUN LAMP exert an invigorating and balancing action on the metabolic processes.

So well authenticated are the beneficial effects of Quartz Light Therapy to-day that every member of the medical profession should acquaint himself with the pertinent facts.

For the most recent literature on Quartz Light Therapy fill in and mail the request blank.

BOOK REVIEWS

(Continued from Page 1062)

and, from its size, comprising some twelve hundred pages, one would expect a rather complete review of modern gynecology. Unfortunately, this is not so. After reviewing the volume, one is reminded of the earlier books on gynecology with an attempt to make it look more modern by adding some of the more recent advances.

In Bland's book, the unimportant commonly obscures the essential. Many recognized modern operative procedures are woefully lacking. In the field of medical treatment little is said about such new methods as dyes, galvanism, diathermy. The book is profusely illustrated and many illustrations reproduced are unnecessarily large. Microscopic illustrations are entirely too frequent. In fact, special pathology in general is not sufficiently emphasized.

Pathology and Bacteriology of the Eye. By E. Treacher Collins and M. Stephen Mayou. Review copy supplied by the publishers, P. Blakiston's Son & Co. For sale by advertisers in this issue.

The first edition was a volume in the International System of Ophthalmic Practice published thirteen years ago. This one is a separate and independent work, greatly enlarged, in which the recent developments in the pathology and bacteriology of the eye are included.

Several of the chapters, namely the ones on inflammation and degenerations, have been entirely rewritten, while many changes have been made in the remaining chapters. Those to be especially noted are the observations on slitlamp microscopy and further additions in glaucoma and hypertony.

The illustrations are extremely good and carefully chosen. The index is well arranged so that it can be used as a convenient reference in the pathology and bacteriology of the eye.

The book is highly recommended as a reference, as well as a guide in the study of the pathology of the eye.

The Physiology of the Mind. An interpretation based on biological, morphological, physical and chemical considerations. By Francis X. Dercum. 287 pp. Illustrated. Review copy supplied by the publishers, W. B.

Saunders Company. 1925. For sale by advertisers in this issue.

This book, reviewed in its first edition, has been increased from 150 to 287 pages by elaboration in each chapter, a consideration of the doctrine of relativity in its relationship to the subject, and a barbed appendix on Freudism. The extended essay has been rearranged in chapter form and reads more easily than the first edition.

Heredity in Nervous and Mental Disease. By Association for Research in Nervous and Mental Disease. A series of investigations and reports. Vol 3. 332 pp. Illustrated. Review copy from the publisher, Paul Hoeber. For sale by our advertisers. Price \$3.75.

This is number three of the series of reports by the Association for Research in Nervous and Mental Diseases. As in the others, it consists in a series of papers presented by members and guests, each paper or group of papers being followed by discussion and questions. The general consideration of the subject of inheritance is followed by chapters on the pathogenesis of heredity and familial disease of the nervous system, on the pathological aspects of the same, on heredity in the psychoses and a concluding essay on heredity as exemplified in literature. One of the most interesting papers is Stockhard's on the experimental production of degeneracy. Working with guinea pigs, "alcohol acts as a selective agent to bring out a group of unusually strong specimens. . . . Should one desire to apply these experimental results to the human alcohol problem, it might be claimed that some such elimination of unfit individuals had benefited the races of Europe, since all of the dominant races have a definitely alcoholic history."

The Practice of Pediatrics. By Charles Gilmore Kerley and Gaylord Willis Graves. Third edition. Review copy by courtesy of the publishers, W. B. Saunders Company. For sale by advertisers in this issue of California and Western Medicine.

In collaboration with G. W. Graves, Charles G. Kerley presents a new edition of his "Practice of Pediatrics," which shows many improvements and additions since it last appeared in 1919. Improvement in printing has added to the clearness of the text and the comprehensibility of the contents, and a re-arrangement of the

(Continued on Page 1078)

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES

A general hospital of 275 beds for women and children. Thirty beds for maternity patients in a separate building, newly equipped.

Complete services of all kinds for women and children. Infant feeding a specialty.

House staff consists of three resident physicians and eight internes.

Accredited by the Council on Medical Education and Hospitals of the American Medical Association.

Institutional member of League for the Conservation of Public Health.

The oldest school of nursing in the West.

3700 California Street
San Francisco

BOOK REVIEWS

(Continued from Page 1077)

material has lead generally to a more logical grouping than that previously used.

The miscellaneous collection of ills designated as "rheumatism," unfortunately, still persists, though assuming the more pretentious name of "rheumatic diathesis." The title of the chapter on "Muscles, Bones and Joints" is a misnomer, for it contains nothing at all on muscles, one single page on joint diseases, and mentions only two bone affections.

It is to be regretted that gymnastic and physio-therapeutic methods were dropped from this edition; on the other hand, the disappearance of unclassified diseases is noted with gratification. The fact, that it has been possible to eliminate this chapter completely, stands as a tribute to medical progress during the past few years.

Major changes stand out in the chapters on infant nutrition. Special emphasis is placed on artificial feeding, food properties, physiological requirements and charts, bacteriology and chemical analysis and considerable space is also devoted to evaporated milk.

Possibly the greatest advance made lies along the lines of blood chemistry; the causes and treatment of pertussis; pyloric obstruction with its differentiation between spasms and hypertrophy and corresponding treatment; hydrocephalus as classified by Dandy; rickets on the basis of vitamins as well as calcium and phosphorus balance; Diphtheria with its toxin-antitoxin immunization; scarlet fever with its Dick test; Dochez immunsera; and finally, diabetes with its insulin treatment.

The use of x-rays is assigned a prominent place in diagnosis and transfusion in the treatment of many ailments, a great number of which were formerly beyond medical help.

Pathogenic Micro-organisms. By William H. Park, Anna Williams and Charles Krumwiede. Complimentary copy supplied by the publishers. For sale by advertisers in California and Western Medicine. Price \$6.50.

The recent (eighth) edition of this standard work is of doubtful justification, although the revising of chapters on immunity freshens the book, and increases its usefulness from the practical viewpoint. The work of the local New York Board of Health in active immunization against diphtheria is given in considerable detail. Few noteworthy advances in bacteriologic technic are noted, but there is an improvement in bacterial grouping. Bacteriophage is briefly considered. The chapter on complement fixation is disappointing.

A New Vitalait Product

B. Acidophilus grown with lactose. An extremely high bacterial count is brought about by the addition of just the correct proportion of lactose.

Cultures are sent direct-by-mail to the patient. Information gladly supplied.

The
VITALAIT LABORATORY

333 So. Fair Oaks Ave.,
Pasadena

753 Flood Building
San Francisco

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

Phone Mission 196 and Burlingame 76

"EVOLUTION is contrary to theology, which may account for some of the animosity it has aroused, but it is not contrary to religion. Theology is man-made, religion is not. . . . It is much more flattering to me to think that we are evolving into something better than that we were created perfect in the garden of Eden and fell into disgrace afterwards; even a man who would construct a machine which would go wrong so quickly and so thoroughly would be called a poor mechanic. The Universal Force, which is creating all things, is belied by such implication." . . . "Those who would legislate against the teaching of evolution should also legislate against gravity, electricity and the unreasonable speed of light and also should introduce a clause to prevent the use of the telescope, the microscope and the spectroscope or any other instrument of precision, which may, in future be invented, constructed or used for the discovery of truth."—Luther Burbank.

ARLCO—POLLENS

were originated to make possible the scientific study of hay fever.

They made available *for the first time* a proper assortment of individualized diagnostic and treatment pollens—permitting thereby differential diagnoses, specific treatment and the development of an authentic literature on

HAY FEVER

The number and diversity of pollens have been constantly increased until they now cover the more essential requirements of the entire country.

But the constant seeking and studying of new pollens will continue in order to permit in future even finer distinctions of diagnosis and to assure still more accurate treatment.

R for--when summer comes

Thousands of mothers are thankful to their physicians for prescribing Dennos—especially during the trying summer months.

The method of preparation requires cooking. The starch in Dennos acts as a protective colloid. Dennos babies seldom develop fermentative diarrhea.

The cereal of Dennos is largely whole wheat, which aids in the retention of the calcium and magnesium salts and often produces a better gain in weight.

Mount Zion Hospital
AND
School of Nursing

2200 Post Street - - - - - San Francisco, California

A General Hospital of 170 beds, thoroughly equipped, all modern facilities. Free Clinic and Out-Patient Department. Accredited by American Medical Association and Standardized by American College of Surgeons. School of Nursing offers excellent opportunities to young women desirous of training for the nursing profession, and is accredited by the California State Board of Health.

Activities

Mount Zion Hospital Staff announces a weekly schedule of ward rounds, operative clinics, and special exercises, including a weekly staff conference to consider clinical problems of unusual interest. Visiting and out-of-town physicians are cordially invited to attend these exercises. Details of weekly programs may be obtained by telephoning West 7200 (Mount Zion Hospital), Franklin 1507 (S. F. County Medical Association), and Douglas 62 (California Medical Association). Following are the days on which the special exercises are held:
Monday 9:00 a. m.—Medical Ward Rounds. Samuel H. Hurwitz, M. D.
Tuesday 8:00 a. m.—Weekly Staff Conference.

Tuesday 9:00 a. m.—Urologic and Cystoscopic Examinations. Louis Clive Jacobs, M. D.
Wednesday 8:30 a. m.—Operations. Charles G. Levison, M. D., and Harold Brunn, M. D.
Thursday 8:30 a. m.—Eye, Nose and Throat Operations. Aaron Green, M. D., and Herbert Cohn, M. D.
Thursday 9:00 a. m.—Medical Ward Rounds. Emilo Jellinek, M. D.
Friday 8:30 a. m.—Clinical X-Ray Conference. Lloyd Bryan, M. D.
Friday 9:00 a. m.—Pediatrics Rounds. E. Chas. Fleischner, M. D., and Ralph Kuhns, M. D.
Friday 9:30 a. m.—Prenatal Clinic. Louis I. Breitstein, M. D.

To Our Customers

We maintain fully equipped commercial and research laboratories with facilities for all classes of analytical determinations. These additions to our plants have made it possible to conduct routine quantitative tests on all of our products, thus insuring you against fatalities due to hap-hazard production.

In addition to medical gases we also manufacture a full line of intravenous and intramuscular medications and are prepared to make up special formulas.

We solicit your co-operation in the ethical advancement of intravenous medications as well as anesthesia.

Distribution of Physicians in the United States—
Raymond Pearl, Baltimore (Journal A. M. A.), says that because the physician cannot be socially and economically set wholly apart as different from the rest of humanity, his life and circumstances are subject to the flow and interplay of general economic circumstances. In looking, therefore, for the fundamental causes underlying the present difficulty of an excess of urban and a defect of rural physicians, Pearl reviews what have been the major economic and social movements affecting the two moieties of the general population which live in these two situations. From his figures it is evident that on the basis of recent behavior, each addition of \$100 to the average per capita wealth of a region means that approximately one physician per 30,000 of population will come into the region and start business, while, for each decrease of \$100 in the average per capita wealth, approximately one physician per 30,000 of population will move away to try his fortune elsewhere. This mathematical approach to the simplest and most general economic factor in the situation lends support certainly to one aspect—the financial and economic—of the evidence presented in the report of Mayers and Harrison. The evidence shows that, disregarding all distinction between urban and rural location, the regional distribution of physicians in the country is in close accord with the general economic status of the several regions. Further, the value of all farm property per capita of rural population in each geographic region may be taken as an index of the relative wealth and prosperity of different farming regions. On this basis it is apparent that generally the exodus in recent years of physicians from the rural locations, which has given so much concern, and precipitated the present discussion, had had associated with it a definite and marked decline in the per capita real value of farm property. In short, it is seen once again that the behavior of the physician in the conduct of his affairs betokens a considerable degree of good economic common sense. In 1923 physicians were

For Sale, Bargain. Notice to the Healing Profession

A first class convalescent home, well advertised and well patronized. High reputation. Can be converted easily, if desired, into a maternity hospital or some other medical utility. A four-story building, fine architecture, beautifully and centrally located in the heart of San Francisco, where property is daily rising in value. Just like new and with all modern built-in features. Plenty of closets, cedar chests, spacious corridors, fire escapes, with plenty of exits. Electric bells in all rooms, with speaking tubes and register. Dumb waiter, large kitchen with all facilities, garden front and rear, bay view from one side and panorama of San Francisco on the other. High and dry and full of sunshine. Office equipment, all sorts of tools, including gardening. Splendid heating and lighting system. 27 elegantly furnished rooms, some in mahogany and walls to match and hardwood floors, 3 sun porches, 4 bath rooms, 4 toilets, garage, barn, etc. 25 beds, all occupied and paying from \$300 to \$400 per week. Net profit to right party 50 per cent. I hold a building permit for more wards and roof garden, but am called East on important matters. If you ever dreamed of a gold mine here it is. A bargain at \$30,000. All I ask is \$25,000. \$8000 is a mortgage and \$17,000 must be in cash. 870 Fell street, Phone Hemlock 2220.

fewer in proportion to population in these small towns (essentially rural) communities than they were in 1906. In only one region (East North Central) is the slope of any physician trend line upward, and there only slightly so. In every case in which there is a detectable difference, the downward slope of the physician trend line is less steep in the case of the towns of less than 1000 population than it is in case of towns of from 1000 to 2500 population. But the differences in slope between the physician trend lines for the two groups of towns (under 1000 and from 1000 to 2500) are all small, and probably not significant statistically. In every case but one (Middle Atlantic) the trend of one or both of the physician lines very closely parallel the trend of the real value of farm property. In the Middle Atlantic group of states, the slope of the farm property line is distinctly steeper than that of either of the physician lines. But in general it is clear that in nearly all parts of the country the relative rate at which the available medical service in rural areas has declined in recent years has been almost exactly the same relative rate that has measured the decline in rural wealth, as indicated by the real value of all farm property. Summarizing the discussion to this point, it may be said that whether one looks at the distribution of physicians relative to large geographic regions, or at the movement of physicians away from rural communities, the same outstanding fact emerges. The economic situation of the region, as such, or the change of the economic situation in time, parallels the facts regarding the relative frequency of physicians. It is difficult to escape the inference that the former is one of the primary causal factors in the production of the fact observed about the latter. The physicians behave, in the conduct of life, about as any group of sensible people would be expected to. They do business where business is good, and avoid places where it is bad. Like any other normal person, the physician wants to make a decent living. Experience has shown him that it is harder to do this in the country than it is in the city. Therefore, he either sticks to or moves to the city. Another point emphasized is that in the major portion of the United States it made no significant difference in the mortality rate of a community in 1920 whether that community had few or many physicians per unit of population. Two morals suggest themselves from this result. The first is that perhaps the chief social and human value of the physician is in alleviating suffering rather than in preventing death, at which last task he must in every case ultimately fail. The second is that we seem to have here in some part a mathematical demonstration of the wisdom inherent in the now proverbial remark to the effect that while there is a great difference between a good physician and a poor one in respect of the results of their activities, there is no significant difference between a good physician and no physician at all.

SANTA BARBARA COTTAGE HOSPITAL

"A Splendid Hospital in an Ideal Location"

Location—Santa Barbara, California, where ocean and mountains meet. Climatic conditions are perfect.

Metabolic Department—Diabetes and Metabolic Diseases are made a specialty.

Roentgen and Radium Department—Complete equipment for treating any malignant or non-malignant condition.

Cardiac Department—The equipment of this department, as well as the location of the hospital, makes conditions excellent for patients suffering from cardiac disturbances.

School of Nursing—The diversity of the work done by the hospital offers exceptional inducements to the prospective student. The Louise Savage Knapp Hall for Nurses, where the students live, is not surpassed in California.

PROTEIN EXTRACTS IN PASTE FORM

FOR the maximum of convenience in the diagnosis of hypersensitization to proteins, use the Parke, Davis & Company line of Protein Extracts, Diagnostic.

These Extracts are put up in the form of paste with a glycerin-boric acid base. They are supplied in soft-tin, collapsible tubes with a narrow outlet, so that a quantity no larger than a pin-head can be removed for the test without touching the remainder.

The technique is extremely simple. All that it is necessary to do is to scarify the site of the test and apply a small quantity of the paste with the end of a sterile toothpick. No other form of protein extract can be so easily applied without jeopardizing the accuracy of the test.

As a further convenience these Protein Extracts are also put up in groups, so that the physician can test the patient's susceptibility toward five or six of the proteins at once, thus materially economizing his own and his patient's time.

THE line consists of 149 individual Protein Extracts, of which 100 are from foods, 6 from seasonings of various kinds, 13 from pollens, 17 from bacteria, 10 from hair, wool, or feathers, others from horse serum, bovine serum, and tobacco; and a number of grouped pollens not represented in the list of individual proteins. Control material is also supplied, consisting of the glycerin-boric acid base only--no protein.

We shall be glad to send you our 40-page booklet on Protein Sensitization. Write for it.

INSULIN · LILLY

TWO NAMES ALWAYS ASSOCIATED

In the minds of diabetic specialists in the United States, the name **Insulin** is very closely associated with the name **Lilly**.

In May, 1922, The Lilly Research Laboratories began co-operating with The Insulin Committee of the University of Toronto in the development of a process for the manufacture on a large scale of a pure, stable, uniform, high-grade preparation of Insulin. Within a few months several thousands of the clinicians in this country were receiving from the Lilly Laboratories ample supplies of Insulin for experimental work.

ILETIN (INSULIN, LILLY)

Iletin (Insulin, Lilly) was the first preparation of Insulin commercially available in the United States.

The name Lilly on pharmaceutical and biological preparations inspires confidence because for nearly fifty years it has stood for scientific products, ethically advertised and economically distributed.

Iletin (Insulin, Lilly) is supplied in 5 c.c. and 10 c.c. ampoule vials, U-10, U-20 and U-40.

All Lilly Products are distributed through the drug trade

THE HAPHAZARD RESPONSE

THE normal, healthy individual is he whose bowels have, as a matter of custom, the impulse to move.

When, as a result of haphazard attention to "Habit Time" the bowel is permitted to become negligent, we have what is undoubtedly the principal cause of the prevalent constipation.

When this condition becomes acute, a cathartic is generally resorted to. This causes irritation of the intestines, the irritation sometimes causes a partial paralysis, the habit of daily movement is interrupted, and another recruit is secured for the army of cathartic users.

To break the cathartic habit and restore the normal function, correct diet and exercise are necessary, and a mechanical lubricant is valuable.

PETROLAGAR provides this mechanical aid. It is a palatable emulsification of mineral oil and agar-agar, which helps educate the bowel to a normal "Habit Time" by providing a soft, easily passed fecal mass, giving perfect lubrication, and diminishing the possibility of leakage.

The agar now being used in PETROLAGAR is an American made agar—a superior product, free from starch, which affords at least 25 per cent additional bulk.

PETROLAGAR has been accepted for New and Non-official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

PETROLAGAR is issued as follows: PETROL-AGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

DESHELL STARCH- LESS AGAR FLAKES

So much interest has been created in the superior American made agar used in PETROLAGAR that we have decided to place it on the market as DESHELL STARCHLESS AGAR FLAKES, for the physician who, in certain cases, may wish to prescribe agar.

DESHELL STARCHLESS AGAR FLAKES are produced in a modern American factory on the California coast.

They are free from impurities, sterilized, free from starch—which affords at least 25 per cent additional bulk.

DESHELL STARCHLESS AGAR FLAKES are unusually palatable.

They can be obtained on prescription from any pharmacy.

Mechanics of Back Strains—Z. B. Adams, Boston (Journal A. M. A., July 25, 1925), reviews the mechanics of the joints in the different regions of the spine, in order to show the effect of the shift of their relative positions to one another, on the stress brought on the ligaments, and thus to show where strains usually occur. The region of the spine in which the strains most commonly occur is the low cervical region. Strains in the thoracic spine are not common. This region is well braced by the ribs. When there are severe distortions, as in scoliosis and in Pott's disease, occasionally there is pain due to strain; but when the deformity develops slowly and is constant, there is surprisingly little pain. At the dorsolumbar junction, one of the most limber spinal sections, there are frequent strains, chiefly in the round and hollow-backed type of person. There are but few cases which show symptoms that can be attributed to the midlumbar spine. The ability to hold the back in the best position to avoid strain certainly depends, to a large degree, on how the body trunk is poised on the feet, knees, and hips. First of all, patients should be shod properly, so that the weight is not thrust down on the heads of the metatarsal bones. This does not mean alone the avoidance of high heels, but it means a shoe long enough to avoid pressure of the vamp seam on the metatarsal shafts and heads, preventing their being raised. It means no cramping of the toes. The weight should be carried on the foot in good position, with the arch of the foot held up, and the leg rotated outward, so that the pivots of the knee and ankle are in the same plane; the knees straight, not in hyperextension. This allows the trochanters to be held back and the femoral necks to approach the pelvis, with the normal, forward inclination of 15 degrees, and this forward push props the acetabula upward and forward, and diminishes the possibility of backward tilt of the hip bones and pelvis as a whole. The proper treatment of these back strains involves getting the muscles into condition. At the same time, patients should be trained to stand in the proper position, so that their bones support the weight. The muscles hold them there. When the ligaments have been torn, it is analogous to a sprained ankle, or when

A place where your patients can find attractive surroundings with adequate medical service and supervision.

Dunning S. Wilson, M. D., Ky. U. of L., '99, is in charge of the Medical Department, which is equipped with complete X-ray, actinic ray, chemical and bacteriological laboratories for diagnostic and therapeutic work.

When your patients are tired of home or hospital send them to French Lick for final recuperation.

Write for Booklet

badly stretched, to a chronic flatfoot, and the cure is not always an easy or rapid process to accomplish. In the acute cases of low back strain, a surprising amount can be accomplished by adhesive strapping on the skin, to bind the gluteal muscles together and prevent the backward tilting of the pelvis. In the severe cases in which real damage has been done, and the ligaments have to shorten and repair, braces and corsets must be used; but one should not lose sight of the importance of developing the muscles, the anterior abdominal wall, the psoas and glutei, as well as the quadratus lumborum and erector spinae, and get the skeletal frame into the position in which it can support the weight at the best mechanical advantage. When the back symptoms seem to have developed as the result of a congenitally defective fifth lumbar vertebra, locking of this section of the spine by bone-graft or fusion is necessary to get permanent relief.

Electric Cataract—Walter S. Franklin and Frederick C. Cordes, San Francisco (Journal A. M. A., July 25, 1925), emphasize this point: In dealing with electrical burns about the face and eyes, the possible development of a cataract must be considered for a period of two years. In industrial cases, this possibility should be reported. The lenticular changes of an electric cataract are rather characteristic, the anterior cortex together with the deeper layers of the lens being involved. The opacities as a rule are flaky, although sometimes finely granular. The voltage causing electric cataract may vary from 220 to 50,000 volts. The eye nearest the site of the burn usually shows the most marked changes. Electric burns may cause serious changes in the globe without the production of a cataract.

Figure It Out for Yourself

Who will suffer the loss of a malpractice action? Who will pay your judgment?

If you do not carry protection you must employ your own attorneys at a fee that would probably pay the premium on a Medical Protective Contract for many years. You will lose time — gain undesirable notoriety — lose money — impair your working efficiency by worry and in the end you may lose and be obliged to pay a judgment — which means a blow to your home, bank account, good name and practice.

Will you continue to expose all that you possess to some disgruntled patient, or will you be prepared for the emergency when it arises by having a Medical Protective Contract?

The cost is small but the satisfaction great

For Medical Protective Service have a Medical Protective Contract

What is Nonspi?

NONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless, NONSPI need be applied, in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

The Selection of a Physician

The selection of a physician for an operation or as a family doctor, is usually made with some care. We consult those who have employed physicians and are governed largely by their recommendations. But having selected a physician, we follow his advice. We trust him even to the extent of submitting to operations that may have serious results.

THE POINT IS, WE TRUST THE MAN
WHO KNOWS

Now, doctor, the institutions and the firms advertised in this Journal were carefully investigated before their announcements were printed here. The medicinal products were submitted to laboratory tests before they were accepted by the Council on Pharmacy and Chemistry.

On this same principle, that patients trust you about matters with which you are informed, so your publishers urge you to trust their judgment and *buy goods from the advertisers who are admitted to these pages.* Other considerations being equal, you should give your advertisers PREFERENCE because you know they are believed to be trustworthy. Don't speculate or experiment! Trust the APPROVED firms and goods.

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Fully Guaranteed - - Troubleproof

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a lamp in back of the ruby bull's eye located in the calling station visible to the patient, a lamp over the door in the corridor, a red pilot lamp in diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob is restored to off position by the nurse.

The push and pull emergency switch is used by the nurse only when she finds the patient in a critical condition and needs immediate assistance. The nurse, pulling out the button of the emergency switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station, and wherever desired. This emergency call is restored, when answered, by pressing the button of the switch, which extinguishes all the green lights. If desired, an audible buzzer may be connected to the emergency switch.

The duplex convenience outlet furnishes a connection for portable electric devices such as examination or reading lamp, electric fan, etc. Two appliances may be connected to this outlet at the same time.

Better Work Better Service

Trojan Washer

Trojan Extractor

These are the two factors that make the laundry department of the modern hospital so valuable.

Other advantages come from the ability to keep down costs; the ability to function with a minimum supply of linen; the ability to get the quality desired, and the ability to control the process and thus insure that the life of the goods will not be unreasonably shortened by injurious methods.

Troy laundry equipment has been designed with an ideal in mind—to enable the modern hospital to plan and equip their laundry department so that it is practical, economical and serviceable.

Our entire staff, engineers, designers and salesmen, all strive to make every hospital installation a perfect one on each of the above mentioned points.

May we serve you? A request to our nearest office will promptly bring a representative.

We cordially invite you to visit our exhibit in booths 623-724, at the A. H. A. convention at Louisville, Oct. 19 to 24.

FOR THE PATIENT WHO BALKS AT BRAN

ZED

The same patient who registers a decided dislike for bran gladly takes to ZED. For ZED is a delicious laxative biscuit in which the coarseness of the bran is hidden by the fine flavor of whole wheat.

In addition, milk, natural fruit and vegetable extracts are used in the blending of ZED to make it tasteful and appealing—and also to supply important mineral elements.

Thus the patient with a marked antipathy to bran finds himself with a marked liking for ZED. There is nothing in ZED to remind him of that "straw-like" taste he has mentally associated with bran. There is everything in ZED to make him like to eat the amount you advise.

We will be glad to supply to any physician on request a full-sized package of ZED for trial purposes.

Tonic Neck Reflexes in Tuberculous Meningitis in Children—I. S. Wechsler, New York (Journal A. M. A.), has observed the tonic neck reflexes in a little less than half the number of cases of tuberculous meningitis studied. They occurred with greatest frequency in children below 3 years of age. The sign is of physiologic and anatomic and not especial pathologic significance. Any lesion at the midbrain level may, on occasion, give rise to the reflex. That it was found in a number of cases of tuberculous meningitis is merely clinical proof of what is known of its pathology, namely, that it is frequently or preponderatingly a basilar meningitis. Wechsler has not elicited the sign in other forms of meningitis. It occurs rarely in few other clinical entities in children. The sign, when present, is always consistent and is a true physiologic reflex, although it may be elicited at one time and not at another.

*Tempting
the
Convalescent's
appetite*

THE appetite of the convalescent patient is a "finicky" thing — it tires so easily of the foods that the patient needs to build him up.

Knox Sparkling Gelatine combines with the necessary foods—milk, eggs, vegetables, fruit juices and broths—and makes an almost endless variety of delightfully dainty dishes.

And recent laboratory tests have shown that gelatine preparations, because of their ease of digestion and their real food value, actually improve the general physical condition of the patient.

To safeguard against impurity and disturbing acidity, it is essential to specify Knox Sparkling Gelatine, the Highest Quality for Health.

A number of special recipes for convalescents have been prepared by a recognized authority and will be sent free to doctors and hospitals upon request. Address the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

NOTE—From the raw material to the finished package, the family of Knox takes pride in producing the highest quality of Gelatine.

ANNOUNCEMENT

The Ideal Metal Furniture, the only complete factory for the manufacture of High Pressure Sterilizers and Disinfectors west of Madison, Wisconsin, is now in production, located at the Central Manufacturing District, Los Angeles, California. Mr. Wm. Wiley, for twenty-one years superintendent of the American Sterilizer Company, Erie, Pa., general superintendent, and Mr. Leo Oakey, for years connected as a Sterilizer and Hospital Furniture Engineer for the Scanlan Morris Company, is assistant superintendent. The R. L. Scherer Company, exclusive sales and service representatives for California and Arizona.

The quality of the Ideal product, improvements and adaptability from the standpoint of modern Hospital Furniture and Sterilizers, makes this line a natural desire in the minds of all Hospital superintendents investigating our product. Full value and quality in every article.

All books received are promptly acknowledged in this column. Such acknowledgment is the only return California and Western Medicine feels obligated to render in return for the courtesy of the sender. Selected books believed to be deserving of comment will be reviewed solely in the interests of our readers. Our advertising columns are open to publishers of acceptable books for such further statements as they care to make.

Diseases of the Bronchi, Lungs, and Pleura. By Frederick T. Lord, M. D. Second Edition, revised, with the addition of a chapter on Pulmonary Tuberculosis. Illustrated with 107 engravings and 3 colored plates. Lea & Febiger, Philadelphia and New York. 1925.

The Ophthalmic Year Book, Volume XXI, containing bibliographies, digests, and indexes of the literature of ophthalmology for the year 1924. Edited by William H. Crisp, in collaboration with a large editorial board. Published by the Ophthalmic Publishing Company, Chicago. 1925.

Jahresbericht Über Die Gesamte Innere Medizin Und Ihre Grenzgebiete. Bibliographisches Jahresregister Des Kongresszentralblattes Für Die Gesamte Innere Medizin Und Ihre Grenzgebiete Herausgegeben Von Der Schriftleitung Des Kongresszentralblattes Fünfter Band Bericht Über Das Jahr, 1922. Berlin Verlag Von Julius Springer, 1925.

Is Man Natively Criminal?—This question was propounded, discussed and its implication largely endorsed at a recent international gathering of educated persons.

Booth Tarkington (American Magazine) takes the subject for a text in a serious article that challenges the interest and attention of all who are concerned with the welfare of the human race:

"If it be true," says Tarkington, "that we are natively criminal, then boyhood must be a period of conflict between the boy and the trained adult. The latter calls

himself society, and makes the laws, while the boy (according to the expert's conclusions and the old wives' tales, too) is still so new in the world that he cannot help being strongly inspired by the criminal impulses of which he principally consisted when he was born.

"In other words, it is natural to him to be an outlaw, and, since what is not natural is artificial, his parents' duty is to train him to lead an artificial and uncongenial life of decorum, instead of the logical one of crime for which nature intended him.

"If that view be the correct one," continues this distinguished author, we have some traditional conceptions to revise. We shall have to alter our whole sentimental position in regard to youth.

"Our fond and romantic fancies about children must be reformed and all the tender idealism of childhood stored in our older literature and art abandoned."

After bringing the question clearly before his readers by several illustrative stories about boys, told in his inimitable style, Tarkington concludes that man is not natively criminal, but that beginning with conception, each child reproduces all stages of evolution (from the ameba to what we are.) "That is to say," concludes the author, "a boy is not a criminal: he is the history of mankind; and, in that light, with what profound interest, with what solemn respect may we not view him! And thus, in that same light, when we look at a new baby, we may display a better intelligence of what we mean when we say, as we sometimes do, 'How, wise he looks!'

"At one time or another most of us have been rather oddly puzzled, even a little disturbed, by the strange look of a very ancient and withheld wisdom that some babies have. 'How queerly old he looks!' we say. 'If he could only tell us all he knows!' And it may be that then we hint at something more than we ourselves know. For when we gaze down, wondering, at that old, old look in the eyes of a new-born baby, we are looking at the first man that ever walked—the oldest man in the world!"

The Mechanical Part of Professional Service

Is often more important than you may consider it

ALL the skill and all the knowledge that you use in diagnosing refractive errors may avail your patient nothing if the mechanical work of the manufacturing optician does not measure up to the same high standard you set for yourself in your professional practice. Choosing the source of supply for your optical prescription work is therefore an important part of the service you render.

Grinding the Lenses

IN our mechanical work you can have the utmost confidence. Here we are specialists in every department of making glasses from grinding the rough blanks to delivering the finished product to your desk or to your patients. For twenty-five years we have been serving the profession and the profession only, and serving them so well that our clientele has grown with almost unbelievable rapidity.

Cutting and Edging

YOUR freedom from mechanical difficulties is assured when you send your prescriptions to a RIGGS house. Your best interests are our only concern, and if you are not already acquainted with the superior features of our prescription service, may we urge you to give us an early trial. Nothing we could say will be so convincing as an actual demonstration of our ability on your most perplexing cases.

Assembling the Finished Glasses

Wrapping for Safe Delivery

Step by step—Every safeguard, every precaution on every necessary operation of spectacle making, is taken to insure glasses in accordance with the prescription you write. Every detail of construction must pass not one, but many rigid inspections. Quality of materials and workmanship is the unbroken rule from start to finish.

SERVING ONLY REGISTERED REFRACTIONISTS

Radium and Oncologic Institute

1052 West Sixth Street

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

J. W. Warren, M. D., Roentgenologist

E. D. Ward, M. D.

REX DUNCAN, M. D., Medical Director

The Nursing Situation is summed up by the Editor (N. Y. Journ. Med.) in these words: 1. The number of nurses is not equal to the demand for their services. 2. There are many specialties in nursing—operating-room, obstetrical, psychiatric, public health, contagious disease, tuberculosis, and so on for a long list of specialties. 3. A skilled nurse who understands the post-operative care of cases of major surgery is the product of long training; and three years is none too long to develop that type of nurse. 4. The nurse who is highly trained deserves special recognition with the title, "registered nurse," and the privileges and social standing which go with that title. 5. The demand for highly trained nurses exceeds the supply. 6. In nursing, as in any other line of work, an undersupply of workers leads to undue independence both in accepting cases and in continuing with them under unpleasant conditions. 7. The average highly trained nurse is a specialist who confines her activities to certain hours and certain duties. 8. Many persons object to having a trained nurse in their homes because of the necessity of having to have "someone to wait on the nurse." 9. There is a very great field for the services of nurses who are less highly trained and who are willing to do some kinds of housekeeping in addition to the care of the sick. 10. There is a grave danger that unskilled nurses, like incompetent healers, may pretend to a knowledge which they do not possess, and may endanger the health or life of the patient and the reputation of the attending physician or surgeon. 11. There are great difficulties in the way of establishing several degrees of fitness for nursing and of credentials of capa-

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

DISCUSSION OF THE ETIOLOGY, SYMPTOMS AND PROGNOSIS OF ARTERIOSCLEROSIS

By JOHN PHILLIPS, M. D., *Cleveland Clinic, Cleveland, Ohio*

INTRODUCTORY NOTE

DOCTOR JOHN PHILLIPS of Cleveland, Ohio, was a guest of the California Medical Association at the 1925 session held in Yosemite National Park, and delivered this important message on certain phases of arteriosclerosis, at one of the general meetings.—EDITOR.

ARTERIOSCLEROSIS, with or without an associated hypertension, is a condition which occurs so frequently after middle life that it often occasions grave concern, not only to physicians, but also to the laity. In fact, after the age of 45 most of the tragedies of life are arterial in origin; a fact which has given rise to the oft-repeated statement that "A man is as old as his arteries." The writer proposes in this paper to discuss some of the general features of arteriosclerosis, particularly the symptoms, as he has observed them in a general and consulting practice.

Many individuals have well-marked arteriosclerosis for years, without experiencing any apparent impairment of health; and if it is uncomplicated by a high blood pressure or by impairment of renal function the condition is not incompatible with long life.

Arteriosclerosis most frequently affects the aorta and its branches; appearing with comparatively less frequency in the cerebral and the mesenteric vessels. It is important to remember that well-advanced arteriosclerosis may be present in certain vessels, such as the aorta or cerebral arteries, while the radial, brachial, and femoral arteries may give no evidence of sclerosis. The vessels of the extremities may be rigid and tortuous, while the intima of the aortic arch is smooth. Generally, however, the condition is widespread and affects all the arteries throughout the body. If an arterio-capillary fibrosis (Gull and Sutton type) is also present, the patient has arterial hypertension, and eventually sclerotic kidneys will develop. O'Hare and Walker have called attention to the fact that in cases of essential hypertension which apparently are free from arteriosclerosis of the arteries which are accessible for palpation, there may be a considerable degree of sclerosis of the small blood vessels. These authors conclude that, while their results definitely "establish the fact that the peripheral vessels play little or no part in hypertension," "they do show, however, a definite relationship between small vessel sclerosis, as indicated in the retinal arteries and high blood pressure." As they state, therefore, the condition of the retinal arteries should be considered a fair index to the condition of the small vessels throughout the body.

The pathological condition of the larger vessels produced by arteriosclerosis may be summarized as follows: There may be small, yellow, non-elevated areas of fatty degeneration beginning in the tunica intima. Gelatinous areas may be scattered over the intima, appearing particularly at the orifices of the arteries. These may fuse into larger plaques and at times may undergo calcification. There may be areas of atheromatous softening which project above the level of the intima, thus causing a roughening of the inner surface of the vessel. Coincident with these changes, the tunica media becomes atrophied and sometimes shows foci of necrosis and areas of calcification. The adventitia becomes thickened and indurated. As a result of these changes, the artery becomes elongated and tortuous and may show aneurysmal bulgings. In arteriosclerosis of the Gull and Sutton type, our knowledge of the changes in the capillaries has been greatly enriched by capillaroscopy.

ETIOLOGY

Many factors, of which we are still ignorant, undoubtedly play a part in the etiology of arteriosclerosis. Undoubtedly, heredity plays an important role. Many patients are born with defective vascular tubing. We have all seen families, in every member of which arteriosclerosis has developed at an early age. In considering the importance of heredity, however, it should be borne in mind that the occurrence of fatal cases of arteriosclerosis in several members of a family may have been due to the fact that they all lived in the same environment, were exposed to the same infections and had the same faulty habits of living and eating. Syphilis is the most important single factor in the etiology of localized arterio-

sclerosis. The majority of aneurysms of the aorta are due to syphilitic infection. Other infectious diseases, such as typhoid fever, as has been emphasized by Thayer, scarlet fever or influenza or the presence of localized foci of infection may cause arterial changes. Arteriosclerosis due to these causes is not always associated with hypertension. In my experience with out-patients in hospital practice I have been impressed with the frequent occurrence of arteriosclerosis in young men, who, at an early age, were compelled to do heavy manual labor, and who harbored foci of infection, such as infected tonsils or teeth. As a rule, the arterial changes in these patients were not associated with hypertension. Intoxicants, such as alcohol, lead, tobacco, or the toxins of gout tend to promote the development of arteriosclerosis. On the basis of my own experience, I do not believe that alcohol is as important an etiological factor as tobacco. Overeating, because of the resultant obesity, is responsible for many cases of arteriosclerosis, especially those associated with hypertension.

The role of diet in the etiology of hypertension and arteriosclerosis, aside from the production of obesity, is to a degree uncertain. In spite of recent studies by Mosenthal and others, in which they disclaim any marked relation of protein intake to the blood pressure, clinical experience in cases of hypertension in which the patient has been accustomed to a heavy protein diet over a prolonged period, and in which the symptoms have been somewhat ameliorated by the diminution of proteins, makes one still question the final value of a study of a series of hospitalized patients for a limited period of time.

A very real danger in some cases is that of under-feeding, with resultant anemia, and Mosenthal sounds the warning that, in order that the health and strength of the patient may be maintained, the amount of diet should be regulated according to the hemoglobin content of the blood, which should not fall below 80 per cent. It should be borne in mind also that, in regulating the diet, the prime essential is weight reduction and, therefore, an undue proportion of carbohydrates should not be prescribed in place of protein.

As for Allen's conclusions regarding the influence of sodium chloride on the production of hypertension, here again it would appear that observation of the effect of the elimination of salts in hospitalized patients is not a sufficient criterion. Allen's findings as to the value of the elimination of salts in the treatment of high blood pressure have not been confirmed by most other observers. As O'Hare and Walker state: "The only reason given for the almost universal restriction of salt in treating hypertension is based on the assumed decreased viscosity of the blood resulting therefrom. But this is mere assumption and not proved or accepted. Perhaps the close relation between chronic nephritis (with salt retention) and vascular hypertension is responsible for the salt reduction treatment. Perhaps it is pure empiricism or a clever method to prevent over-eating by rendering the food less palatable."

Certainly, general clinical experience does not appear to assign any important etiological role to the intake of salts; and the same may be said regarding the fluid intake. The essential etiological factor,

as far as diet is concerned, would appear to be the weight factor. Obesity is the real enemy rather than this or that food constituent.

In recent studies to discover which, if any, metabolites might have a pressor effect and, therefore, might be a factor in the production of hypertension, Major and Stephenson state that the guanidine compounds normally excreted by the urine have a marked and prolonged pressor effect. Moreover, they have found that patients with essential hypertension, as well as those with chronic nephritis associated with hypertension, have a decreased output of guanidine bases.

Whatever may be the cause of hypertension, however, whether it be renal disease, infection, the retention of certain metabolites, such as guanidine, overeating, or the stress and strain of modern life, it is eventually followed by arteriosclerosis. Undoubtedly, essential hypertension (hyperpiesia) leads to arteriosclerosis. Advanced arteriosclerosis with aneurysms may occur in small children. Recently, I saw a child 5 years of age with thickened tortuous arteries, with well-marked sclerotic changes in the retinal vessels, and with a systolic blood pressure of 220 and diastolic of 130. At autopsy the typical changes of advanced cardiovascular renal disease were found.

In addition to these types of arteriosclerosis, caused by infection, or by heredity, or by hypertension, the arteriosclerosis of old age should be mentioned—the type which Albutt calls "descrescent" or involutionary. This type, in which the arteries are thickened, tortuous and markedly calcified, is not necessarily associated with hypertension.

The role of the endocrines in the production of hypertension and arteriosclerosis has not been established, although that some relationship exists is suggested (1) by the undoubted etiological importance of obesity; (2) by the arterial hypertension which is associated with the menopause; (3) by the fact that hypertension associated with an adenoma of the thyroid gland is relieved by thyroidectomy; and (4) that worry, and prolonged emotional strain, which, as Cannon believes, are directly related to the function of the endocrine organs, are mentioned as causes of hypertension and arteriosclerosis.

SYMPTOMS

In considering the symptoms of arteriosclerosis, although, as a rule it is a generalized condition affecting all the vessels of the body, yet, as stated above, the pathological changes may be much more advanced in certain areas of the body than in others. The symptoms of arteriosclerosis are due to the following causes: (1) A reduction in the blood supply to an organ, as the result of which the function of the organ is impaired and fibrous tissue gradually replaces the normal parenchyma; this process is well illustrated by the fibrous myocarditis, which results from coronary sclerosis. (2) Necrosis, which occurs when the sclerosis of the vessels has advanced to the point of obliteration. This is most marked when the affected vessels are the so-called "terminal" or "end-arteries" as, for example, in the heart or brain. In the brain this necrosis produces areas of softening; in the extremities gangrene may result. (3) Angiospasm, which is more apt to occur in sclerosed

than in normal vessels. Angiospasm of the extremities gives rise to pain and ischaemia, such as is seen in Raynaud's disease. Spasm or intermittent closing of the cerebral vessels causes transient attacks of aphasia, monoplegia, or hemiplegia, or, at times, convulsions—the so-called vascular crises described by Pal of Vienna.

It is obvious from the above description that the symptoms of arteriosclerosis can be best considered in their relation to the various areas which may be involved. In some patients in whom the condition is generalized, the only symptoms may be a gradually increasing weakness, loss of mental acuity, failing appetite, increasing pallor, and loss of weight.

The symptoms of *cerebral arteriosclerosis* depend on the fact that the blood supply of the brain is diminished, with resultant impairment of the nutrition of the brain. It requires, however, a considerable diminution of the blood supply to produce symptoms, for the brain is supplied with a much greater quantity of blood than is actually necessary for its normal function. The first symptoms produced by a decreased blood supply to the brain are those which are characteristic of neurasthenia, i. e.: undue fatigue, mental and physical, after a moderate day's work; diminished capacity for mental concentration; a marked inclination to worry over trifling business difficulties or about the health. The patient is often irritable and forgetful, and at this stage may become much depressed, believing that he is no longer of any use in the world; he may even show suicidal tendencies. The lack of memory is manifested by difficulty in the choice of words and particularly by forgetfulness of recent events, in contrast to memory of the experiences of childhood which is retained much longer. The loss of memory may gradually increase until the patient becomes unable to take part in any conversation beyond saying "yes" or "no." Sometimes the patient, who may previously have been very fastidious about his dress, becomes very neglectful of his personal appearance. These general symptoms indicate a sclerosis of the anterior cerebral artery.

In cases in which cerebral arteriosclerosis is associated with hypertension, headache, vertigo, tinnitus aurium, insomnia and at times vomiting, may be striking symptoms. The development of intense headache in the later years of life is due to sclerosis of the cerebral vessels more frequently than to any other cause. The presence of a well-marked arcus senilis and the discovery of characteristic changes in the retinal vessels by ophthalmoscopic examination may reveal the true cause of the headache. Vertigo, either severe or manifested simply by a sense of insecurity of equilibrium, is a common symptom. Some of these patients complain of vertigo when they are in certain positions, particularly when lying flat on the back. In cases of hypertension associated with arteriosclerosis, noises in the ears (tinnitus aurium) are nearly always present at some stage of the disease.

In cases in which the arteriosclerosis is associated with high blood pressure, there may occur attacks of transient monoplegia, hemiplegia or aphasia due to intermittent claudication or closing of the cerebral vessels, these attacks sometimes being associated with migraine. These "larval apoplexies," as Sir

Clifford Albutt has called them, may be accompanied by convulsions, and they are often followed within a few months by cerebral hemorrhage.

In many patients there is evidence of this hypertonic contraction of other vessels, such as the angina which indicates spasm of the coronary arteries, abdominal pain indicating the involvement of the mesenteric arteries, and cramps when the vessels of the extremities are concerned.

The differential diagnosis in these cases is not difficult. A sudden hemiplegia, as a rule, is caused by hemorrhage, by embolism, by thrombosis, or by intermittent closing of the cerebral arteries. The first three of these conditions cause destruction of brain tissue with resultant loss of function. The last causes a temporary impairment of function in the part of the brain affected—a halting of brain function as the result of the temporary closing of the channels which convey the blood, a condition comparable to intermittent claudication. The transitory character of the hemiplegia, therefore, is the striking feature in cases of vascular spasm.

The *middle cerebral artery* is the vessel most frequently affected. Lesions of this vessel will cause contralateral hemiplegia and hemianesthesia and—especially when the artery on the left side is affected—both motor and sensory aphasia.

Lesions of the third division of the *left middle cerebral artery* will cause alexia with hemianopsia or hemiachromatopsia dextra. Thrombosis of the *posterior inferior cerebellar artery* will cause unilateral paralysis of the larynx and palate, dysphagia, contralateral hemianesthesia and homolateral trigeminal anesthesia. Obstruction of the *basilar artery*, or aneurysm of this vessel or its branches, may give rise to a train of symptoms and physical signs which are usually grouped as characteristic of bulbar paralysis. Thus, there may be occipital pain, pupillary rigidity with myosis, disturbances of articulation, dysphagia, dyspnoea, tachycardia, arrhythmia, drooling, explosive laughter or crying; paralysis of the fifth, seventh, eighth, ninth, tenth, eleventh, and twelfth cranial nerves; and sometimes unilateral convulsions, hemianesthesia and hemiataxia with hemiplegia alternans. Sclerosis of the *internal auditory artery* affects the cochlear and vestibular apparatus, causing labyrinthine deafness, with vertigo and vomiting. If the posterior cerebral artery is affected the patient may complain of vertigo, temporary hemianopsia, scintillating scotomata with headaches and temporary amblyopia. Sclerotic changes in the *ophthalmic artery* cause arcus senilis in the cornea, visible changes in the retinal vessels in the nature of tortuosities, indentations, thickenings, obliterations, minute hemorrhages and yellowish spots due to degeneration of the lamina vitrea of the choroid; while among the other occasional findings are thrombosis of the central artery of the retina, glaucoma and intractable senile conjunctivitis. Arteriosclerosis of the *cerebellar vessels* may lead to cerebellar ataxia, with asthenia, atonia, and astasia.

True *aneurysms of the cerebral arteries* are quite uncommon, as is shown by the fact that among 501 aneurysms Crisp found aneurysm of the intracranial arteries in only seven cases. Beadles collected 555 cases of cerebral aneurysms and classified them in four groups: (1) Those in which the first indica-

tion of a cerebral lesion had been an apoplectic attack due to rupture of the aneurysmal sac. (2) Those in which fatal apoplexy had been preceded by symptoms suggesting a cerebral tumor or other cerebral lesion. (3) Those in which there had been indications of a cerebral tumor only. (4) Those in which there had been no symptoms whatever during life, the aneurysm having been discovered at autopsy. In over one-half the cases the first symptoms noticed had been those characteristic of apoplexy.

Some cases of aneurysm of the cerebral arteries have presented such symptoms as headache, dizziness, loss of memory, or even insanity; in fact, in many of the reported cases the aneurysm was found at autopsy in patients who had died in hospitals for the insane. When the aneurysm affects the basilar artery, focal symptoms due to involvement of the cranial nerves may be present; but when other arteries are affected, the focal symptoms are not definite enough to facilitate diagnosis. At times the general symptoms of brain tumor—headache, vomiting, and choked disk—are present, while in rare cases a murmur has been heard on auscultation of the skull. Very few aneurysms larger than a marble have been described, and one the size of a hen's egg would be considered very large.

Involvement of branches of the main trunks mentioned above may give rise to similar but less pronounced symptoms and physical signs. Sclerosis of the *spinal arteries* may produce motor and sensory disturbances which are paraplegic in character, with loss of sphincteric control and diminished reflexes.

Arteriosclerosis of the *ascending aorta and the aortic arch* as a rule is easily recognizable clinically by the following characteristic signs: (1) There may be pulsation in the suprasternal notch and in the first and second interspaces to the left and right of the sternum, together with a high position of the subclavian arteries. Occasionally a diastolic impact may be felt. (2) The retromanubrial and paramanubrial dulness is increased. (3) The second sound of the heart in the aortic area has a tympanitic or bell-like quality. (4) On fluoroscopic examination the mediastinum is seen to be widened and the heart to lie transversely. (5) There may be signs of pressure on the trachea such as inspiratory stridor and of pressure on the veins within the thorax such as dilatation of the superficial vessels of the upper part of the chest. (6) In some cases there are signs of insufficiency of the aortic valve.

In making the differential diagnosis it is important to bear in mind that a substernal goiter may cause widening of the mediastinum, and pressure on the trachea and the vessels, with resultant inspiratory stridor and dilation of the veins. In acute aortitis the patient may complain of intense substernal pain so that acute pericarditis and acute mediastinitis also must be considered in the differential diagnosis.

In patients with *atherosclerosis of the aorta* pain simulating an angina may occur, this being due in some cases to an infringement on the lumen of the coronary arteries at their point of origin from the aorta. If the dilatation of the aorta reaches a sufficient size to be termed an aneurysm, then, in addition to the previously mentioned signs, there will be

a tracheal tug; signs of pressure on the left recurrent laryngeal nerve, with resultant paralysis of the vocal cord; of pressure on the esophagus with dysphagia; of pressure on the trachea with hoarseness, paroxysmal cough and inspiratory stridor; of pressure on the spine, with severe intercostal neuralgia; of pressure on the cardiac sympathetic nerves, with inequality of pupils; of pressure on the superior vena cava, with occlusion of the vessels arising from the arch.

Aneurysm of the *ascending arch* may be marked by a large pulsating tumor to the right of the sternum. If there is moderate dilatation of the *descending portion of the aorta* the only symptom may be a persistent intercostal neuralgia so that the condition can only be detected by a roentgenological examination. If there is any aneurysm of this portion of the aorta, there may be extreme pain in the back from erosion of the vertebrae, pain in the sides and over the sternum from pressure on the intercostal nerves, dysphagia and pulsation in the back on the left side of the median line and fluoroscopic examination may disclose a circumscribed pulsating expansile shadow.

Arteriosclerosis of the *coronary arteries*, with the resultant gradual impairment of the blood supply to the heart muscle, may lead to a fibrous myocarditis with subsequent decompensation. The most striking symptoms of this condition are attacks of angina and dyspnoea, the latter often being described as cardiac asthma. In these patients with so-called cardiac asthma, the dyspnoea, which is paroxysmal in type, is often accompanied by wheezing or by a true pulmonary edema, usually occurs at night, though it may follow exertion or emotional excitement; the pulse is rapid, small and soft, and the area of cardiac dulness is often widened; and various forms of cardiac arrhythmias may be present. In extreme forms of myelomalacia, cardiac aneurysm or rupture of the heart may occur.

In these cases sudden death from coronary thrombosis may occur. If a smaller branch of one of the coronary arteries is occluded the patient may survive, the striking features in such a case being: (1) Very severe precordial pain, which is transmitted to the arms, to the neck or to the epigastrium; the pain is persistent and very difficult to relieve by morphine; (2) a grayish, ashen color of the face with cold perspiration, suggesting severe shock; (3) a rapid fall of both the systolic and the diastolic blood pressure; (4) mild delirium accompanied by elevation of temperature of one or two degrees; (5) an increase in the size of the heart with at times the development of a faint systolic murmur at the apex and a pericardial friction rub in a limited area, usually to the left of the sternum in the third interspace; and (6) a gradual enlargement of the liver as the result of congestion.

Sclerosis of the *pulmonary artery*, a condition sometimes called Ayerza's disease, sometimes accompanies emphysema and mitral valve lesions. The most striking symptoms are dyspnoea, cyanosis, and repeated hemoptysis. On examination, the right ventricle of the heart is found to be hypertrophied, and the second sound of the heart in the pulmonic area is accentuated.

In sclerosis of the *abdominal aorta*, the patient

often complains of pain and a rigid, tortuous vessel can be palpated. If an aneurysm is present it can be felt as a pulsating expansile tumor, above the umbilicus, the pulsation persisting when the patient is in the knee-elbow position. Sometimes a loud bruit can be heard over it. In making the diagnosis it is important to differentiate the throbbing aorta of anemic neurasthenic individuals.

Arteriosclerosis may affect the branches of the abdominal aorta—the coeliac artery, the mesenteric arteries and their intestinal branches, and the renal arteries. The symptoms and signs of arteriosclerosis of the *coeliac artery* and its branches include epigastric pain, vomiting, haematemesis, melena and if an aneurysm is present, an abnormal pulsating mass will be found in the epigastrium. In cases of aneurysm of the *hepatic artery* an incorrect diagnosis as of gall-stones or of duodenal ulcer is usually made. Thrombosis of the *mesenteric artery* causes acute abdominal pain, bloody stools, vomiting and signs of intestinal obstruction. If the *renal arteries* are involved there may be polyuria, albuminuria with casts and sometimes red cells in the urine. Other more advanced cases will present all the symptoms and signs of a contracted kidney, with low specific gravity of the urine, nocturia, albumin and casts, arterial hypertension, and hypertrophied heart.

The signs of arteriosclerosis of the *vessels of the extremities* include thickened, tortuous, often beaded arteries, and in the lower extremities the disappearance of pulsation in the dorsalis pedis and posterior tibial vessels. As a result of the poor circulation, cramps in the extremities are frequent, especially upon walking. Pains and various forms of paraesthesias are often complained of. At times there is marked acrocyanosis or evidence of erythromelalgia. In the more advanced cases as in diabetes, gangrene results.

In cases of generalized arteriosclerosis with arterio-capillary fibrosis (Gull and Sutton type) arterial hypertension with subsequent arteriolar nephritis is present. In these cases the heart is hypertrophied, and in the later stages impairment of renal function is evidenced by the fixed specific gravity of the urine, diminished phthalein output, and high blood urea.

PROGNOSIS

The prognosis of arteriosclerosis varies according to whether or not it is associated with high blood pressure. Patients with advanced arteriosclerosis may live to a good old age if the condition is not associated with arterial hypertension. The most frequent causes of death are (1) cerebral hemorrhage, or occasionally cerebral thrombosis; (2) myocarditis with broken compensation; (3) angina with or without coronary thrombosis; (4) uraemia; (5) an intercurrent disease such as pneumonia; (6) some associated condition, such as rupture of an aneurysm, thrombosis of the mesenteric vessels, general sepsis due to gangrene of the extremities, etc.

In considering the immediate prognosis in cases of arterial hypertension associated with arteriosclerosis, two classes of cases might be considered: (1) Those without demonstrable impairment of renal function; and (2) those with impairment of renal

function. In the first group the systolic pressure varies from 180 to 200 and the diastolic from 75 to 100. The heart is hypertrophied and the vessels tortuous. These patients may live for twenty to thirty years after the condition is first discovered, but eventually they will show renal impairment. In these cases death may be due to cerebral hemorrhage, angina or myocardial failure. As a rule the first objective sign of cardiac defeat is a marked lowering of the systolic blood pressure. In other words, a lowering of the systolic pressure with resultant lowering of the pulse pressure is a sign of weakness of the cardiac pump. Even after the signs of myocardial failure have manifested themselves, rest and the judicious use of digitalis may improve the patient's condition so that he may live for years, provided he recognizes his limitations and adapts his physical activities accordingly.

In the second group in which renal impairment is the result of an arteriolar nephritis, the outlook as to the duration of life is not good. These patients have a high systolic pressure varying from 180 to 220 or even higher, while the diastolic varies from 110 to 160. In a recent study of 484 cases of arterial hypertension, sixty-four cases had a diastolic blood pressure of 130 or more, and of these, thirty-six cases, or 53.4 per cent, were dead within three years. Of 115 patients with a diastolic blood pressure of 120 or more, 50 or 43.5 per cent were dead within three years. Patients with a phthalein output of less than 20 per cent for two hours, or whose blood urea taken while fasting is 50 mgms. per 100 cc. or more, seldom live for more than two years. The outlook is especially grave in patients in whom the blood creatinin is above 5 mgms. per 100 cc. Retinal hemorrhages and albuminuric retinitis also are very unfavorable prognostic indications.

Of course there are exceptional cases in which the grave prognosis is not fulfilled, but these exceptions only serve to emphasize the general rule.

Cleveland Clinic.

Sugar Content of Blood in Runners Following a Marathon Race—Marathon runners who competed in the race of 1924 and showed blood sugar levels below normal were placed on a moderately high carbohydrate diet during this year's training season. In addition, they were advised to take a large amount of carbohydrate twenty-four hours before the race. Another group of runners who developed symptoms of weakness and hunger in the 1924 race were studied during this year's training season with the purpose of determining, if possible, at what stage in a twenty-five-mile run the symptoms of hunger and weakness were likely to develop. It was found that this was apt to occur between the fourteenth and eighteenth miles. Therefore, in addition to being advised to eat moderately large amounts of carbohydrate before the race, these athletes were supplied with glucose candies to be eaten from time to time while running. In addition, they were supplied with tea containing a large amount of sugar at stations along the course. The blood studies made by Burgess Gordon, L. A. Kohn, S. A. Levine, Marcel Matton, W. de M. Sriver, and W. B. Whiting, Boston (Journal A. M. A.), showed normal sugar levels in all runners, in contrast to the low figures obtained last year. There was also a striking improvement in their general physical condition. In a number of instances the running time was faster than in the year previous and the participants finished in better position. It seems, therefore, that the picture of exhaustion, weakness, shock, and other symptoms of hypoglycemia following prolonged effort may be prevented by the adequate and timely ingestion of carbohydrate.

IS REMOVAL OF THE GALL-BLADDER OR DRAINAGE THE OPERATION OF CHOICE? WHY?

SURGICAL "CONVERSAZIONI" BY INVITED AUTHORS

INTRODUCTION BY THE EDITOR

Every medical editor receives many letters from his readers, complaining of the diffuseness and prolixity of authors. It is said that many medical essayists generalize too much and too frequently "go a long way around" to avoid making a definite statement. Most of our readers who take the trouble to express themselves to the editor want to see more short, clearly and unequivocally expressed, messages about practical problems of the practical "bedside doctor." Many of them tell us that they are as much interested in a clear statement of the best practice in a given situation as they are in a statement of some new discovery—more, in fact, than in a new discovery not yet in shape to be utilized by the practicing doctor. All doctors take pride in the slow, tedious work of our research colleagues in efforts to add new knowledge to the available store. They like to see this work published in appropriate places, and wherever it approaches the plane of practical utility they like to see it in our magazine.

We wonder if their position is sound? In any event, after repeated conferences with editorial councilors, we have hit upon the plan of trying out a series of medical and surgical "conversazioni," the subjects to be practical and sharply limited, and the discussions to be limited to a few hundred words each. The only way the editor may judge the usefulness of this or any other innovation is by the reaction *we receive* from our readers. So you will help in promoting the usefulness of CALIFORNIA AND WESTERN MEDICINE if you will write and give us your frank reaction as to whether these "Conversazioni" are useful enough to be continued. Now, to our subject: IS REMOVAL OF THE GALL-BLADDER OR DRAINAGE THE OPERATION OF CHOICE? WHY?

ANDREW STEWART LOBINGIER (Merritt Building, Los Angeles) — Removal of the gall-bladder *and* drainage best meet the indications for an infected liver and pancreas. More harm has come of cholecystectomies done where there was no pathological justification than in any other field of abdominal surgery. Only surgeons who have devoted years of conscientious study to these infections are competent to deal with the surgery of the gall-bladder and ducts. Physicians (as distinguished from surgeons) have been abundantly justified in their criticism of the ill-considered work and unhappy results so often following cholecystectomies without drainage, and in cases where adequate pathology did not exist. There is no group of infections anywhere in the body where fine judgment, founded on intelligent understanding of the pathology and pathologic physiology, is more imperative.

There is no field where the floundering operator of scant pathological training and experience has more melancholy failures charged against his stupidity. It seems incredible, in the light of the work of Graham, Peterman and Mann, that we should still see the literature burdened with verbose screeds on cholecystostomy versus cholecystectomy. Surgeons who have worked and written authoritatively in this field know what to do in the right hypochondrium from the pathology which they find there. They meet the problem competently when they are confronted with it.

In infective hepatitis and cholangitis we have recommended the removal of the gall-bladder down to the junction with the cystic duct, fixing in a firm walled drain, to be kept there for six or eight weeks. Partial cholecystectomy, with protracted drainage of the liver and ducts, we believe, will be the surgery of the future for hepatitis, pancreatitis, cholangitis, and cholecystitis. The technique of this drainage has been described elsewhere ("The Principle and Technique of Drainage in the Surgery of the Gall-Bladder and the Bile Tract," California State Journal of Medicine, February, 1924).

PHILIP K. GILMAN (Stanford Medical School, San Francisco)—Given a proper understanding of the pathology of the biliary apparatus, there is no need for discussion of the above subject. One should no more drain and leave an infected gall-bladder than an infected appendix.

If the infection is confined to the gall-bladder only, cholecystectomy suffices. If the infection involves not only the gall-bladder but ducts as well, drainage must be secured in addition to removing the removable infected organ—the gall-bladder.

This drainage is best secured through either the cystic duct or the duct plus the adjoining portion of the gall-bladder, and should be maintained long enough to insure its object. If this drainage be not carried out, it is partially secured sooner or later by failure of the sphincter at the duodenal end of the common duct. The patient, however, during this period continues to suffer from the infection in the ducts. Of even more importance is the question of drainage, with pancreatitis, added to the cholecystitis and hepatitis.

Cholecystectomy plus drainage is the operation for infection of the gall-bladder and ducts. Experience is needed and familiarity with the appearance of the organs in the right upper quadrant, both in health and disease. Without these, exploration of the upper abdomen should not be attempted. Ill-advised surgery, as well as insufficient surgery, result here in grief and criticism.

H. H. SEARLES (University of California Medical School, San Francisco) — The question offered for this discussion does not include the diagnosis of the disease for which the patient is to be treated. Therefore, we have to consider all of the conditions where such measures should be employed. Varying types of pathology in the gall-bladder and biliary system, or different stages of the same type, call for different plans of surgical treatment. Both cholecystectomy and cholecystostomy are accepted surgical procedures. There are positive indications for the use of either the one or the other.

In the ordinary case of chronic cholecystitis, with or without stone formation, simple cholecystectomy offers the most rapid and complete relief from symptoms, and is accompanied by only slight risk. In cases of long standing, with advanced liver and pancreatic involvement drainage of the common duct must also be done.

On the other hand, operation should be limited to a palliative cholecystostomy in those cases of acute progressive cholecystitis which show a rising pulse, temperature, and leucocyte count, in spite of attempts to check the process by rest, hot stupes,

etc. In such emergencies, exhibiting a true picture of the "acute abdomen," cholecystectomy has been found by costly experience, even in the hands of the most skilful, to result in a very high mortality. We must, therefore, resort here to drainage alone. When, as a result of this procedure, inflammation has subsided, secondary cholecystectomy is generally required for a cure.

Cullen, analyzing a fairly large series of cases of gall-bladder disease of all types treated by cholecystostomy, has found, in a careful follow-up, that a very large percentage of these patients were completely relieved of their symptoms. He feels that with such results the safer, simpler operation of cholecystectomy is to be preferred in the hands of the average surgeon. Yet we find, in most hospitals today, cholecystectomy being employed in the treatment of the ordinary case of chronic cholecystitis, while cholecystostomy assumes the lesser role of a palliative procedure for emergency cases.

GEORGE THOMASON, M. D. (Hollingsworth Building, Los Angeles) — The correct answer to the above question is both affirmative and negative, depending entirely upon the circumstances under which the choice has to be made. The wisest decision in many cases taxes the judgment of the operator, and necessitates the summoning of every detail of his personal observation, as well as the facts gleaned from the experience of others, for the last word has not yet been said in reference to gall-bladder surgery. The history of radical gall-bladder surgery does not yet extend back far enough to make it possible to lay down dogmatic rules which shall govern in all cases of biliary disease. Conflicting opinions emanating from various centers confirm this statement. However, it is evident, as further data accumulates on this subject, there is more and more earnest plea for extirpation of the gall-bladder in the vast majority of cases rather than for drainage.

Careful study of the literature, back over a period of some years, reveals the fact that most surgeons of large experience in gall-bladder surgery present quite uniform records of removing 90 per cent of involved gall-bladders, and draining only about 10 per cent. It seems probable that in future there will be some slight increase in the percentage of drainage cases as precision and classification are a little further developed.

Personally, I believe that in any patient with a history at any time of common duct involvement there will be promise of better permanent results from drainage. Once a common duct has been the site of obstruction or inflammatory change it is a potential source of danger, and a gall-bladder remaining available for attachment to the stomach or duodenum to facilitate the biliary flow from the liver to the intestine may prove of inestimable value, often to the point of being life-saving. No doubt, in the future, recourse to this method of supplying biliary drainage will be more frequently utilized than in the past.

In acute cholecystitis and empyema of the gall-bladder the dangers of cholecystectomy are altogether too great, and drainage should be the opera-

tion of choice, with probable necessity for cholecystectomy at a varying period later.

Earlier recognition of gall-bladder involvement, either with or without stones, with removal of the gall-bladder before the stage of complication ensues, will result in permanent cure and obviate whatever necessity there might otherwise be for drainage.

E. F. HOOVER (861 Sixth Street, San Diego) — Hard-and-fast rules can no more be laid down here than elsewhere in surgery. Cases must be individualized and carefully studied before opening the abdomen, and again when the laparotomy is done; a quick, careful survey will then determine the proper procedure for the individual case.

Cholecystectomy is probably the operation of choice, in the chronic case, when the gall-bladder is easily accessible and when it is apparently so diseased as to preclude its return to a normal state following drainage.

Certain acutely ill patients who present a profound toxic state, accompanied by a rising differential and total leucocyte count, rising temperature and pulse, and which at operation will present a gall-bladder in the pre-gangrenous state, must only be drained.

In other patients it is not always technically or mechanically possible to do a cholecystectomy, without adding too great a burden to the patient's recuperative power. Nor has the last word been said as to the function of the gall-bladder, or as to the consequences of cholecystectomy.

C. H. Mayo, in a series of 242 cholecystotomies, reports 53 per cent cured. This is strong evidence that the operation has merit for the selected patient. He reports 219 cholecystectomies, with 71 per cent cured. Eighteen per cent better results, but not a perfect score.

It is well to remember that the greater amount of abdominal surgery, of necessity, is not done by the limited specialist, who too many times, in his remarks, is inclined to be unmindful of his own humble beginnings and his ever-present failures.

FRED R. FAIRCHILD, M. D. (Woodland Clinic, Woodland, California) — A general answer to the above questions cannot be given. To answer intelligently, many assumptions must be made and numerous correlated conditions considered.

If the question proposes to determine the relative operative risk—assuming one or the other type of operation for all classes of gall-bladder disease—the answer would be that drainage is the safer procedure.

If the question proposes to determine the relative efficacy of the two procedures—assuming one or the other type of operation for all classes of gall-bladder disease—the answer would be that removal is the method of choice.

But no experienced surgeon operates under the above limitations. The problem is not general. It is specific. Each case must be treated according to its own determining factors. The operator of experience and wisdom does not know until the abdomen is opened whether he will drain or remove the gall-bladder or remove the gall-bladder and drain the biliary channels.

From personal observation I feel that drainage

rarely cures. It gives excellent temporary relief. Unless there are factors—hepatitis, dehydration, lowered kidney function, jaundice, very acute infection, etc.—adding material hazard to cholecystectomy—the gall-bladder had better be removed. If there is evidence of chronic infection—hepatitis, pancreatitis, etc.—the cystic duct should also be drained.

If the correlated conditions add material hazard to cholecystectomy, the gall-bladder should be drained and at the time of election removed. I am not convinced that a positively diseased gall-bladder ever returns to normal. If it does not, its menace as a constant source of focal infection will probably be greater than the immediate hazard of cholecystectomy.

In cases of very acute gall-bladder disease with unsatisfactory general condition, drainage under local anesthesia, with removal at a subsequent time, should give the best mortality records and the most satisfactory ultimate results.

CLOSING NOTE—Now that you have it before you, what is your reaction? From the standpoint of an editor who reads and attempts to evaluate over a million words of copy a year, it is excellent.

Certainly, it is definite enough, brief enough, and “snappy” enough to please a medical Brisbane.

Do you want more of the same type of “Conversations,” or don’t you? Let the editor know your wishes, and while you are about it, in case you approve, suggest other subjects and state whether or not you would be willing to take part.—Editor.

RECENT ADVANCES IN CANCER RESEARCH

By LUDWIG A. EMGE, M. D., *San Francisco*

(From the Department of Obstetrics and Gynecology, Stanford School of Medicine, San Francisco)

Most of the recent findings point toward a cancer-controlling substance of constitutional origin which experimentally can be increased or decreased at will.

Cancer research has opened up new aspects of cancer treatment which may take on concrete forms as research progresses and which ultimately may materialize into more successful methods of treatment.

DISCUSSION by Edward N. Ewer, *Oakland*; Alson R. Kilgore, *San Francisco*; Herbert W. Wall, *Los Angeles*.

IN bringing this most important subject before the members of this section it is evident that in the short time allotted it is impossible to present a detailed review of the literature on cancer research. Such a review, at best, would involve the discussion of numerous questions which at this stage of our knowledge must be considered as being of academic interest only. I have, therefore, confined myself to the very recent findings which have a definite practical bearing upon the cancer question and which, I hope, may serve you for a better understanding of the intricate mechanism that underlies cancer production and its treatment. To give a clearer picture of the various phases of cancer research, I have attempted to group the findings in such a way that their relation to each other may be clearly understood.

Heredity, unquestionably, plays one of the most important parts in the production of cancer, although this has not definitely been established for man. Maude Slye’s work on mouse cancer proves that cancer tendencies are transmitted just as any

other characteristics are passed on from generation to generation. Her work shows that selective breeding can increase or decrease cancer tendencies to a degree where cancer resistance is either completely wiped out or raised to complete protection. The basic factor must be sought in a substance transmitted in the germplasm. This factor is variable in its degree and duration of existence. It seems to be closely akin to the factors which govern the aging of tissues, but does not necessarily depend upon the age of the individual. It is the aging of tissues which brings certain functions of the body to a standstill and with this event the resistance to cancer decreases or disappears. Therefore, any factors which will favor aging of tissues must also favor cancer production. Among these factors, wasting diseases, such as syphilis or severe typhoid for instance, play a definite role. Also frequent and rapid involutions of an organ productive of cicatrix formation, such as occurs in the uterus and the breasts in rapidly recurring pregnancies exerts a definite influence (Stajano). The experimental proof for this assumption may be found in Carrel’s recent work on antagonistic growth principles of serum and their relation to old age. In these tissue culture experiments with fibroblasts, two factors stand out clearly, one is that serum loses its proliferative activity on homologous fibroblasts as age advances and the other is that this quality is then replaced by a growth inhibiting action on the same tissue. Since fibroblasts form one of the most important barriers against the advance of despecialized cells which ultimately develop into a malignant structure, we may deduct that any factor which tends to weaken the fibroblastic action must also weaken our cancer defense. With this fundamental finding before us we can no longer consider cancer as a local disease, but must assume that we have to deal with a constitutional disturbance. Bard, who expostulates that the malformation of the cell does not accept the influence of vital induction and, therefore, proliferates without limits, merely expresses the same thought in a reversed order. I shall cite further proof during the progress of this discussion that it is not so much the failure of the despecialized cell to accept the moderating influence of vital fluids as it is the disappearance of some highly specialized hormone in these fluids which allows the aberrant cell to proliferate.

Until very recently the interest of workers in cancer research was mainly concentrated on factors governing the mechanism of local cancer formation. We may accept it as an established fact that acute trauma very rarely leads to malignant growth tendencies, otherwise cancer should be rampant among wounded soldiers. The process which incites cells to undergo abnormal growth tendencies is slow and can best be classed under the general term of chronic irritation. Therefore, the many proofs that have been advanced that this or the other substance is the cause for local cancer “possibly all represent partial and different aspects of the truth” (Hegel). That not every species is susceptible to the same irritants has been exhaustively proven by the many failures in producing skin cancers in animals by the continual application of tar or its derivatives. Some species and sometimes only certain groups within

this species will react to a given irritant while others are completely immune. This was most brilliantly demonstrated by Fibiger in the production of gastric cancer by feeding the nematode *spiroptera neoplastica* to rats. While one type of rats would, in the majority, develop gastric cancer, other types only responded occasionally, while still others were entirely immune. Clinically, we observe the same phenomenon in the cancer of chimney-sweeps, laborers in the tar and paraffin industry, in the victims of bilharziasis, in the natives of Kashmir suffering from epithelioma of the abdomen and thighs and in x-ray workers with their epitheliomata of the hands. By no means all the individuals exposed to carcinogenic agents develop cancer. Therefore, the carcinogenic agent seems to be only the mediate and not the proximal factor of this disease (Leitch). Leaving out all discussions of what produces actually the reversion of the irritated cell to an undifferentiated cell of the embryonic type as being at present of academic interest only, we may accept that carcinogenic influences are exerted by any long continued irritation to which certain individuals have insufficient constitutional resistance. We also must accept that experimentally at least an irritant may produce either carcinoma or sarcoma, as has been shown in mice. Therefore, the specificity of an irritant in relation to a definite type of malignancy must be questioned.

A further factor in cancer production aside from a weakening of the constitutional resistance is the lowering of local resistance. I have alluded to this above. Wherever organs undergo periodical fluctuations in size, resulting in premature aging of the connective tissue leading to contractions of tissue fibers, or wherever cicatrix results from acute trauma, the circulation is prevented from coming into normal contact with highly specialized tissue. When this tissue is cut off from the vital fluids, its cells lose their differentiated character and revert to a more embryonal type (Lumière). Such cells then acquire the exceptional faculty for growth common to embryonal tissue. They then begin to proliferate and may produce malignant growth, provided the general constitutional factor of protection is lacking. Proof for the protective influence of connective tissue has been offered by Bierich, who noticed the multiplication of connective tissue fibers after continued application of tar before epithelial proliferation took place. On continued irritation the connective tissue reaction came to a standstill and epithelial proliferation occurred and overcame the connective tissue barrier. This investigator succeeded in stimulating connective tissue growth by one mild exposure to roentgen rays or by repeated injections of arsenic, by which methods he prevented tar cancer formation in animals.

This protective phenomenon is still more strikingly demonstrated by Murphy and Sturm in their experimental transplantation of mouse tumor into the brains of rats, guinea pigs and pigeons. Here transplants took well as long as they were entirely in the brain tissue. Once they came in contact with the ventricle or larger blood vessels a cellular reaction took place and destruction of the tumor occurred. Similarly, the transplanted tumor tissue was destroyed when a bit of autologous spleen tis-

sue was transplanted simultaneously with the tumor tissue. Here again the defensive action of connective tissue is demonstrated.

In attempting to shed further light on the protecting action of constitutional cancer resistance, Pearce and Brown investigated the subject of experimental metastasis. Although their findings have not given us further definite data about constitutional cancer resistance, they confirm that the peculiarities of metastatic involvement are largely dependent upon constitutional differences of the host which govern the nature and distribution of the lesions and the organs affected.

That cancer production is of infectious origin has again recently been claimed by Robertson, who reports the isolation of organisms of the diphtheroid type from human cancer material, with which, in a few instances, he was able to reproduce cancer in mice. Such findings, while of the utmost interest, demand further proof. Just at present they will have to be classed with those of cancer production by irritation, into which class also falls the gastric cancer produced by Fibiger, cited elsewhere. Neither is the infectious theory of cancer production strengthened by artificial tumor production in plants through inoculation with the bacterium *tumifaciens* as reported by Blumenthal and Hirschfeld. While it is true that tumor formation in plants can be produced in this way, it is also true that the resulting growth is not of a malignant type since it lacks both the power of penetration and of metastatic transplantation.

In turning to another phase of constitutional cancer resistance, I will briefly review the observations made recently on immunity in relation to cancer. Spontaneous cures of cancer have again been reported by Trinkler. Experimentally, this phase of cancer research has been investigated recently by Woglom, who could not find sufficient proof that either the stroma, or the parenchyma of the tumor, or the vascular changes occurring with the retrogression of the tumor produce the responsible factor in cancer retrogression. More positive findings were reported by Theilhaber, who concludes that since cancer commonly develops in anaemic tissue, it is necessary to raise immunity by stimulation of lymphoid and red blood cell activities. He, therefore, has employed sun and air baths, diathermy and venesection, in conjunction with surgery and radiotherapy, in order to raise immunity by increasing the activities of the circulatory system. His thirty-two "cures" of his forty-four operative cases which he observed during a period of thirteen years, demand that his assumption deserves attention. Of interest is also the report of Russ, who attempts to raise immunity by the injection of radiated cancer tissue previously removed from the host. His report is optimistic, but, like so many others, awaits the test of time.

Nakahara, who investigated the relation of lymphoid activities to cancer immunity, offers proof that such activities are dependent upon certain stimulating or depressing influences, somewhat akin to those governing sensitiveness to foreign proteins. Agents of a depressing character have a similar influence on transplanted cancer. X-ray exerts such a depressing action when a certain dosage is reached.

Applying his conclusions to clinical medicine, we cannot help but wonder if this principle does not explain the dismal failures of repeated deep radiation with massive doses of roentgen rays, where a patient, who apparently had improved marvelously after one exposure, failed rapidly after further treatments.

Numerous workers have attacked the cancer problem by studying the associated biology. The instances are by far too numerous to be reviewed here, especially so since they fail to give us essentially new information which might be of value to the clinician. The vast majority of the biological phenomena, which appear with cancer progress, must be attributed to secondary manifestations, such as anemia and cachexia. I, therefore, pass over this phase of cancer research and go on to studies of the influence of experimental radiation on cancer.

Leo Loeb has recently reviewed the literature on the effects of roentgen rays and radioactive substances on living cells and tissues. He has come to the conclusion that the main effect of radiation on tumors consists in a direct injurious effect on the tumor cells. A secondary effect is expressed in reactions of the host, which hold in check or injure still further, for variable periods, tumor cells primarily injured by radiation. He also points out that results, in which the number of lymphocytes was increased by radiation resulting in a retardation of transplanted tumors cannot, as yet, be applied to man. That there are other factors than those cited by Loeb has been claimed by Schwarz. This author believes that the specific roentgen ray sensitiveness of some carcinomas is proportionate to the tendency toward involution of the organ from which the growth originated, as, for instance, in the case of the uterus. Also Murphy, Maisin and Sturm hold that radiation of the tumor cell is not the only factor which governs cancer retrogression. These investigators found that autografts of spontaneous mouse cancer, when implanted into an area previously exposed to an erythema dose of x-ray, failed to grow in more than 70 per cent of their trials. Similarly, growing autografts would also disappear in about the same proportion if the tumor and the surrounding tissue had been exposed to an equal dose. On the other hand, autografts exposed to the same dosage outside of the body and then implanted grow progressively in 96 per cent. Their conclusion was that roentgen rays had done no direct damage to the cancer cells. To strengthen their deduction they rayed tumor tissue in situ and then transplanted it, finding that it would grow actively in the new host. Their work has been essentially substantiated by Nakahara, who also noted the increased lymphoid activity over polymorphonuclear reaction in radiated areas.

That cancer transplants will still grow after massive radiation has been claimed individually by Kok and Vorlaender. Both these investigators hold that the activity of rays is, therefore, not necessarily of a local character. They are convinced that it is the smaller (stimulating) dose which incites the production of some defensive substance most likely of the nature of a connective tissue-growth stimulant because connective tissue reactions fail to materialize if this tissue has been damaged by over-massive doses.

It is quite clear that most of the recent findings point toward a cancer-controlling substance of constitutional origin, which experimentally can be increased or decreased at will. This, to my mind, is the most momentous advance in cancer research. The unsolved portion of the problem is to locate the seat or seats of origin of this controlling influence.

Researches under way at present suggest that the endocrine system may be a definite factor in this respect. Although we all realize that the endocrine theories have been worked to death, it, nevertheless, remains a fact that these glands, as a whole or in part, constitute the governors of our most important body functions. We, therefore, cannot disregard the findings which Engel has reported on the relation of the endocrines to cancer growth. Engel has succeeded in inhibiting tumor transplants in mice effectively by the injection of thymus, and to a lesser degree by injections of thyroid derivatives. He found ovarian and testicular products ineffective, but noticed that pituitary substances had a growth-stimulating influence. In his conclusions he points out that these activities are not pharmacodynamic, but hormonal in nature, since they do not depend upon albuminous bodies of high molecular structure, but rather upon abiuretic, well broken down, albuminous products similar in nature to Abderhalden's optones. Engel is very cautious, and sounds a warning in regard to the source of the endocrine materials utilized since their qualitative as well as quantitative effects are governed by age, race and species. In defense of his experimental evidence he cites the beneficial influence of oophorectomy in operable cancer of the breast, which he explains by the retroactive stimulation produced in the thymus. Whatever truth there is in Engel's findings, a vast and hopeful field has been opened for further research. To me it is a sign that we are approaching a solution of the phenomenon which determines the constitutional resistance against cancer. Were it not for the enthusiasm and optimism among the workers in cancer research, we might just as well resign ourselves to be ultimately doomed to destruction by cancer, although such a fate lies so far ahead in the dimmest future that we cannot measure it by our standards of time.

There are numerous other questions on cancer research left undiscussed here because of their highly technical and hypothetical nature. In the main I have touched on the most vital findings which have a direct bearing on the clinical aspect of cancer. In summing up I repeat that recent cancer research has definitely shown that malignancy can no longer be regarded as a local manifestation alone, but must be accepted as a constitutional disturbance. Cancer research has opened up new aspects of cancer treatment which may take on concrete forms as research progresses and which ultimately may materialize into more successful methods of treatment.

Stanford University Hospital, San Francisco.

DISCUSSION

EDWARD NORTON EWER, M. D. (Federal Realty Bldg., Oakland)—Until recently we were advised that the only definite thing known about cancer etiology was the

requirement of a pre-existing irritant lesion. While this does not yet recede in importance, it is interesting to know of the new place in the sun being accorded to heredity and that nebulous factor, constitutional resistance, which seem likely to bring cancer into the class of systemic diseases. Doctor Emge's paper is a clear and timely resume of recent cancer research.

Belief in heredity seems to be gaining ground, but whatever role it plays in the matter is of no practical importance so far as man is concerned, for selective breeding is, of course, out of the question. Human mating is not arranged on a health betterment basis. Eugenics, at present, is only an academic pastime for certain intellectuals.

It is interesting to note the change in view in regard to constitutional tendency; and the passing of the teaching that cancer is, in its beginning, a local disease always amenable to cure by extirpation, if discovered early enough. True, we are still to gauge our treatment according to that view; and the educational propaganda to bring the patient to early treatment must go on. It is shown that local irritations long continued cause cells to lose their normal character and revert to embryonal type when they take on the rapid growth characteristic of embryonal tissue. This displaces Conheim's theory of embryonal rests. Another factor in proof of the constitutional influence and against the Conheim theory, is the occurrence of multiple primary cancers. They are not very common, but many cases have been reported by various authors. Kocher contributed a case of simultaneous primary occurrence in ovary, breast and axilla. Multiple cancers of various types occur at the same time and malignancy of different types as well, not only in paired organs but in those differing in function. Davidsohn reports a case of chorionepithelioma and primary gastric carcinoma existing together. Carcinoma in one place and sarcoma in another have been described.

While then cancer as a systemic disease is almost established, we must, as already stated, continue our attempts at the earliest eradication possible. The so-called "precancerous" stage must be looked for. The denial of a recognizable precancerous condition (Pick and Hansemann) is one of the "great hindrances in the recognition of early carcinoma" (L'Esperance.) It may not be possible to state that a particular lesion will later become cancer, because we have no means as yet to determine the individual degree of constitutional cancer resistance, but we have some facts to guide us in handling these lesions. We know the danger for the future in gastric ulcer. Epidermal and subepidermal tumors of certain types should be excised (Bloodgood). Erosions of the cervix and cervical polyps in the cancer age are portents of evil; and many experienced surgeons are beginning to urge the removal of a uterus, from the cervix of which there is an intractable discharge as the menopause approaches.

The great expenditure of time and money in cancer study is gradually making returns, and we are warranted in looking with confidence for more effective treatment in the early future.

ALSON R. KILGORE, M. D. (391 Sutter Street, San Francisco)—Doctor Emge's excellent survey of recent cancer research leaves one with the conviction that we are still wandering in a maze of more or less disconnected facts. The factor of heredity in the incidence of cancer is coming to be more and more accepted, but the relation of cancer origin and growth to the fibro-blast and lymphocyte mechanisms, to endocrine dysfunction and even to such external influences as radiation, are still largely in the realm of speculation. Many suggestions have come from research along various lines, but we are still unable to correlate the separate bits of knowledge obtained into any connected explanation of the cancer process.

There are, as brought out in this paper, several pieces of evidence pointing to general systemic changes taking place in association with cancer, perhaps resulting from the cancer—possibly causing or predisposing to the development of cancer. There is even some evidence that

experimental cancer may produce immunity against further development of similar cancers.

But, after all, whatever the final verdict of research, for practical purposes in the clinical handling of the disease, the vast majority of human cancers behave as if their origin were purely local. Certainly, the only treatment so far productive of permanent cures has been mechanical destruction or removal of cancer cells before unreachable metastasis has taken place. For the present, therefore, we ought to distinctly recognize two phases of the cancer problem—the research problem for what the future may bring—the public's problem of the present reduction of cancer mortality. In the attack on the community's present cancer problem, we have still to go on the assumption that cancer begins as a local disease and educate our public to recognize the danger-signals of cancer in its early stages.

HERBERT W. WALL, M. D. (6331 Hollywood Blvd., Los Angeles)—Doctor Emge is to be highly commended upon his able manner of handling this most important subject. All of the resources of chemistry, physics, physiology, biology, and the study of immunity reactions, have, during the past few years, been brought to bear upon this problem. Although some things have been achieved, we have yet a long way to go. Experimental work on animals has been productive of many things; oftentimes as much on the negative as on the positive side.

The knowledge that manipulation and compression often produce metastases, must be kept more prominently before us. Even subsequent to operative interference, it must be recognized that such factors are of great importance. Early operative removal of all conditions simulating carcinoma, should be the physician's attitude, without debating unduly and losing valuable time, which so often seals the fate of many a case that comes to us, long after a reasonable diagnosis has been made, and the patient tarried while the family physician failed to urge immediate action. It is the early and uncertain cases that must be recognized, if any material improvement in our mortality is to be brought about. The physician who fails to make a thorough physical examination and then follow up by every known test to arrive at a diagnosis, is guilty of criminal negligence, and his patient will later reap the inevitable consequence. One need not be an alarmist, but simply be on the alert at all times to perceive the significance of his patients' symptoms.

Removal of tissue for pathological examination is impossible in many conditions before the time of operation, and in these cases it should be avoided, if a diagnosis can be made with reasonable certainty by other methods. But where it is necessary in a doubtful case one must be prepared to follow up immediately by the radical measures which the case may demand. In dealing with incipient carcinoma, the two courses open to the physician are: (1) to await further developments, (2) to make an exploratory, to be followed at once by a radical operation if the diagnosis is positive. The first method is often the easier course, and, sad to relate, is still followed by a great many men, and it is one of the factors most directly responsible for the present enormous mortality of this disease. Let us resolutely abandon this attitude, and, by our eternal vigilance and prompt action, cut down the death rate in carcinoma, just as has been done during the past two decades in the case of appendicitis.

DOCTOR EMGE (closing)—I greatly appreciate and agree with the thorough and frank discussions presented here. If my presentation of the subject has given the impression that I advocate any deviation from the accepted radical treatment of isolated malignancies, I wish to go on record right now that I believe in the most radical methods of attack employed at the earliest moment. The subject of this review deals primarily with basic factors in the biology of cancer and not with its treatment. The reason for presenting it was to acquaint the general profession at large with certain advances which ordinarily do not come to the attention of the general practitioner because of the limited time he can devote to reading of specialized journals.

THE PSYCHO-NEUROSES: PSYCHASTHENIA, NEURASTHENIA AND HYSTERIA, WITH SPECIAL REFERENCE TO A CERTAIN METHOD OF TREATMENT

A STUDY OF 310 OF MY PERSONAL CASE HISTORIES

By THOMAS J. ORBISON, *Los Angeles*

A definite constitutional distinction, racial in character, may exist between the psycho-neuroses as found in America and those observed among foreign racial groups, based upon hereditary differences that are psychological as well as physiological.

A study of 310 private patients.

DISCUSSION by *Harold W. Wright, San Francisco; H. Douglas Eaton, Los Angeles; Milton B. Lennon, San Francisco.*

FOLLOWING the first publication of the Training Camp Method (J. A. M. A., Jan. 13, 1912) many letters have been received from various sources, among them a very stimulating one from the late Jno. K. Mitchell of Philadelphia. Further work along this line was encouraged and has been done. This included certain attempts during the war to apply its wider use in rehabilitation work. I have been the more encouraged for the reason that by its exhibition as a therapeutic measure in suitable patients one is able more completely to put to rout all those horrific camp followers of the mind that beset every psycho-neurotic.

Psycho-neuroses are disorders affecting the (combined) psychic, vegetative and sensori-motor nervous systems. They are characterized by dysfunction of the energy-making and energy-conducting (kinetic) apparatus. They do not include the true psychoses (insanities), the true neuroses, nor the sequelae of gross organic lesions—though they may complicate them or ante-date them in the same individual. They are often found in individuals suffering from these disorders and form part of their symptom complex. The great bulk of the Psycho-neuroses is made up of the Neurasthenias, Psychasthenias and Hysterias.

This paper is based upon a study of 310 private patients with their histories—viz.: 127 Neurasthenias; 140 Psychasthenias; 43 Hysterias. Its chief purpose is to again describe and emphasize anew a method of treatment that was thoroughly tried out in thirty of these patients and which affected a permanent cure in twenty-two; “very good” or “excellent” results in three; “improved” in three, treatment not completed in one; apparent cure, but not sufficient time elapsed to be sure in one.

The literature upon this subject will not be dealt with nor statistics invoked. This is essentially a clinical paper dealing especially with the therapeutic phase of the subject, which has been most efficacious in my experience.

A definite constitutional distinction, racial in character, may exist between the psycho-neuroses as found in America and those observed among foreign racial groups, based upon hereditary differences that are psychological as well as physiological. This may account for the different views of Neuro-Psychiatrists here and abroad regarding etiological factors, dominant symptoms and treatment. Biology teaches that “psychological characters appear to be

inherited in the same way that anatomical and physiological traits are; indeed, all that has been said regarding the correlation of morphological and physiological characters applies to psychological ones” (Conklin: Heredity and Environment). This being true it follows that one need not explain the phenomena of the psycho-neuroses as found in America (i. e. their symptomatology) upon the same arbitrary hypotheses, in absence of more accurate knowledge than is at present available, as are accepted (or, demanded) by some of the leaders of thought in Europe.

One other point must be brought out. It is not uncommon to hear even qualified psychiatrists assert that there is no such clinical entity as neurasthenia—claiming that as time goes on more and more cases of “neurasthenia” are found to suffer from some intercurrent disease, e. g., tuberculosis, focal infection, and so on. They reason as follows: A psycho-neurosis is without demonstrable pathology characteristic of known disease. Neurasthenia, if anything, is a psycho-neurosis—ergo: Neurasthenia must be without such demonstrable pathology—which *presumably* it is not; therefore it cannot exist as an entity! Their inference is that all so-called neurasthenias would in fact be something else if our examination were competent.

The fact is, we have long fully recognized as being a truly typical set of medical experience those patients exhibiting the symptom complex which we designate neurasthenia. To deny does not banish them. The underlying principle is that a negation of any of the experiences of life, which are accepted as competent criteria by qualified observers, is more unscientific than the acceptance of them until disproven beyond doubt. Since the time of Beard, who gave it a name, Neurasthenia has been accepted as being a definite set of pathological experiences.

As to Hysteria one finds little or no attention paid to qualitative racial differences in the literature. In my experience most of the hysterias seen in this country were of a much more quiet or depressed type than those stressed in foreign literature. In the forty-three cases of this series remarkably few gave a history of the exhibition of attacks of major hysteria, although several of their family histories included such cases. Comparatively few gave a history of “laughing and crying spells,” and the like.

An analysis of my 140 cases of Psychasthenia brings out a suggestive and perhaps significant fact—namely that an hereditary taint was present in most of them as well as in the Hysterias, but not in the Neurasthenias.

The following very brief sketches will be given as examples of the three types of psycho-neuroses comprising the series that were treated by the Training Camp Method.

I. *Psychasthenia*—Definition: Hyper or hypo irritability, especially of the psychic sphere (using the term irritability in the biological sense of response to extrinsic or intrinsic stimuli) characterized by excessive or exaggerated responses even to the normal every-day stimuli and especially to the psychogenic stimuli involving the emotional sphere (an emotion being the *consciousness* of certain hereditary reflexes taking place within us—supposedly

involving the internal secretory glands and the related vegetative nervous system). *Dominant Symptoms*—Phobias, sense of inadequacy, anxiety, fear in general.

CASE 1. R. O., male, age 36 years, married.

F. H. Father was subject to fits of depression. One of father's sisters committed suicide.

P. H. Diphtheria and typhoid in childhood. Malaria at 23 years. This was followed by a severe nervous disturbance during which he was for one year in a private sanitarium and then took a trip around the world with his father.

From childhood he had been subject to terrors by night and by day—and, like so many children, he told no one of them—e. g., he would, when a child, sit for hours upon the stairs after being sent to bed waiting for the family to retire. He did this so as to see the lights down stairs and hear the voices of the family. When they moved to retire he would scramble into bed and then go to sleep. He continued this sort of thing for years. He remembers one occasion when a story terrified him and he became livid and sat staring for a long time. He states that he became able to handle his own fears fairly well after he grew up. He received a good education and made an exceptional success in banking business.

Present condition began after a recent financial panic during which he worried excessively. He lost sleep and became depressed. His old fears lighted up and he believed he was the cause of his depositors losing their money—this in the face of the fact that his bank was entirely solvent. It became necessary for him to give up his work for a time, as he had become unable to concentrate his thoughts or to form correct judgments.

His dominant symptoms, when first seen by me, were the obsessions of jumping into the water or under passing trains; claustrophobia; fear of driving over a high bridge; sense of self-depreciation and personality shrinkage; poverty of psychic tonus.

P. E. No pathology shown by laboratory tests or brought to light by careful physical examination. There was a functional faulty elimination of intestines and evidence of "sluggish liver."

Treatment—Training Camp Method.

Result—Cure in three months. He became so well that he returned to active business and for years took his place in public and private enterprises. With such a constitutional heritage as this patient possessed, one would rather expect a recurrence in some form at some future date.

This man belongs to a group of patients in which the symptoms were as severe in their way as one sees in many cases of true psychosis. I have repeatedly seen him drive over a high viaduct bridge that was a pet aversion of his. On each occasion he would hide his face in his hands in abject fear and break out into profuse perspiration. At times he would weep. His psychic tonus became so lowered that there existed for a time partial mental clouding which prevented him from writing or reading—he could not concentrate his mind upon anything that required extra effort. His one thought was the intense mental pain he suffered. These are patients who really experience agony of mind. Their one question is, "Will this cloud ever be lifted?

Can I ever again feel as do others?" This sounds very much like what one sees in psychosis. Indeed, it would be surprisingly difficult to answer off hand the question, "What is the difference between many phases of the severe types of psychasthenia and certain true psychotic episodes?"

These patients require all the therapeutic measures at our disposal, in order to bring them back to psychic integrity. This necessitates a true spiritual and mental renovation which involves the eradication of poisonous fears, debilitating phobias and confusing doubts; the renewing of the soil of the mind for the purpose of implanting normal ideas; the nurturing these to the point where new mental habits are formed and the vicious methods of ideation put aside. Then, at last, the hardening process of making the rehabilitated energy-making apparatus function sufficiently long to insure by repeated acts the normal habit and thus its more or less permanent action as a smoothly running machine. The Training Camp of professional pugilists and Amateur Athletic teams do just this for the normal. I have attempted to adapt the method to psychoneurotic.

CASE 2. C. H., 23 years, male, single.

F. H. Father an invalid with chronic heart disease and asthma. Mother and two sisters neurotic—both the latter of the hyper-thyroid type.

P. H. From childhood has been temperamentally reticent, diffident and retiring. Coming to adolescence his ambitions excelled his ability to compete with his fellows. This made him introspective and aggravated his sense of inferiority. At school he did well, specializing in electric engineering. He states that all his life he seemed just to fall short of the ability to "put over" himself. This chagrined him very much, but he could not explain it. For a time he grew fast—this was almost a bony over-growth implicating his hands and face as well as the long bones. He developed a distressing keratoderma of the palmar surfaces of the hands. He was able to enter the U. S. Army service during the war and did his work satisfactorily. Unfortunately he became entangled in a matter that touched his pride and emotional sphere to the extent of bringing back in a wave that overwhelmed him all the suppressed and hidden ideas that were wont to harass him before. It seemed to be proven to him that he really was right to feel unequal to compete with his fellows. This idea enlarged and he developed intense psychic hyper-irritability, characterized by fears, anxiety and self-depreciation. His physical condition became affected and he lost weight and developed neurasthenic symptoms also. His keratoderma became really distressing and added to his feeling of shame. He will talk for hours about his obsessions and fears.

Present condition is distressing and alarming. His family fear psychosis.

P. E. Evidences of old pluriglandular disturbance—pituitary and thyroid. Patient is 15 pounds underweight. Skin is dry and harsh. Hands are very large and palmar surfaces horny and leaky. Facies anxious. Mentally he is depressed, retiring, introspective and shy. He believes he has consistently made a failure of life—not for lack of trying. He has certain ideas regarding the exciting episodes that are obsessive in character. They dominate his life completely.

Treatment—Training Camp Method.

Result—Entire absence of symptoms (including the keratoderma) after four months. The change in this man's personality and character were almost unbelievable. For the first time in his life he can look his fellow man in the eye without fear or any ideas of inadequacy. He has regained his initiative and his place in life as a worker. As he describes it,

"It is good to feel able to get into the game and not to sit on the side-lines."

II. Neurasthenia—Definition: Hyper or hypo irritability, especially of the sensori-motor or the vegetative nervous systems or both, characterized in the former especially by fatigability and in the latter by more or less violent dysfunction of the various organs which are administered by the vegetative system. The lowered tone of the psychic sphere in these cases may be described qualitatively in terms of fatigue. *Dominant Symptom*—Fatigability.

CASE 1. Mrs. M. K., age 25 years.

F. H. Heredity good.

P. H. Entirely well up to five years ago, when she was married. Her first child was born ten months later. After that she began to develop symptoms of fatigue and came to California to recuperate. Upon her return home she had an attack of tonsillitis—"quinsy"—and diphtheria. Was much debilitated. She then developed pain in the left knee. Came again to California. Upon her return she suffered an attack of pleurisy with effusion. A little later she exhibited numbers of purplish, painful noduli, mostly on the legs. They lasted six weeks and disappeared slowly.

Two years ago (previous to my seeing her) she had tonsillitis again. Three months later her second child was born. Three months later, while on a four days' trip, during which she was subjected to intense heat, she became "hysterical." Five months later she suffered a three weeks' frank neurasthenic attack. Immediately following she had tonsillitis and was much run down. She had been under excellent medical care during all of these episodes. No T. B. bac. had ever been found in her sputum—though the attack of pleurisy was most suspicious. The tonsils should, of course, have been removed.

P. I. Patient first seen about a year and a half after the last attack of tonsillitis. Chief complaint is intense fatigability. She finds it difficult to walk one block or go up a flight of steps. She cannot dress her hair because of fatigue. She experiences the visual disturbance, seen at times in neurasthenics, of seeing only half an object—this will only last a few moments or a few minutes at a time. She had had a thorough physical examination by a surgeon and an internist a short time previous to her first visit to me and no pathology was found. My own physical examination elicited nothing new. No stigmata of hysteria were observed. She was much emaciated and weighed 113 pounds. Her muscles were soft and flabby.

Her mental condition is excellent—no phobias, no excessive anxiety or dread, no emotional imbalance. She had been told to "forget it," to "get some new interest in life," to "take a lot of exercise," and so on. She is a very intelligent woman and stated that her family and children gave her enough enthusiastic interest in life, but she found it difficult to tolerate the advice to "forget it" and to "throw it off" and "make the effort to take exercise," when she could not dress her own hair and could scarcely brush her own teeth because of fatigue.

Treatment—First: Complete rest treatment for six weeks. Second: Modified rest with beginning out-of-bed exercises. Third: Training Camp routine.

During the first period she received passive exercises and massage with overfeeding. During the second period the exercise was increased. Then followed the full Training Camp routine. Result—after three months she was without symptoms. She had gained twenty-three pounds, could walk ten miles without fatigue and do all the training routine without distress. I saw her at intervals since then and she has remained perfectly well through several years. I do not know of any recurrence of symptoms.

III. Hysteria—Definition: Hyper or hypo irritability of the psychic and sensory motor spheres with dysfunctions in these spheres, characterized by abnormal psychogenic dissociations and associations. (This is offered as a fairly good working formulation.)

Freud writes, "The characteristic factor of hysteria is to convert the psychic into the physical." Babinski has proposed the name "pithiatism" as a substitute for the name hysteria. It is a combination of two Greek words meaning "persuasion" and "cure." He offers the new name because, as he states, "A phenomenon is hysterical when it can be produced through suggestion and cured by persuasion."

The dominant symptoms of hysteria are dissociations and associations that are abnormal or pathological. For this reason the definition given above seems accurate enough to be acceptable and brief enough to be expedient—therefore more or less satisfactory.

There are normal as well as abnormal psychogenic dissociations that are constantly made use of, e. g., when a microscopist examines his specimen he may keep both eyes open and yet consciously see but one field—the stage of his microscope. He consciously or unconsciously dissociates one field of vision. The same thing happens when the expert wing shot shoots with both eyes open—as he sights along the gun barrel he at once dissociates all his visual fields, except what is really an almost tubular field that takes in his bird. One can readily conceive of a normal becoming an abnormal or pathological process—either in the sensory and motor spheres or both.

CASE 1. J. H., age 24, single, female.

F. H. Hereditary taint: Mother is extremely nervous and emotional; she has suffered several "nervous breakdowns"; two of her sisters have had psychasthenic attacks.

One brother is a confirmed invalid—had disease of spinal cord when a boy; he exhibits phobias and other psychasthenic symptoms.

P. H. Has always been strong and healthy physically. Her psychic hyper-irritability was demonstrated, however, in childhood by numerous childish obsessions. She has always been "nervous," imaginative, decidedly temperamental and a great reader. She never showed symptoms of tic, chorea or other neuroses. She has always been inclined to be athletic and never had any nervous breakdown.

P. I. About three months before I first saw her professionally she suffered with a severe coryza and later laryngitis. This continuing for some time she feared she might "strain her voice." The conversion of her fears into the subsequent dissociation became definite and fixed. She decided to remain quietly at home and not see people. This she did and began not to want to see people—which was quite different from her normal attitude. After two weeks she decided to have her ton-

sils and adenoids removed. This was done and for two weeks more she remained quiet and began to feel better. Then she went to a card party where she had to talk loudly. She says she felt her throat contract more and more as though she were talking against pressure. This frightened her and she wanted to leave. Thereafter she had the symptom of a tight band about the throat, plus asphonia. She has also had fits of crying. Her dominant symptom is aphonia of an hysterical nature.

Reflexes—tendon reflexes are exaggerated. No other symptoms of hysteria were noted in the history, but my recollection is that there was hypaesthesia of one eyeball and of the nasal mucous membrane on that side.

Treatment—Training Camp Method.

She was sent to one of the less frequent beaches with a "trainer," who was instructed as to the kinds of persuasion and suggestion to be employed. I saw her regularly, of course. The daily routine was prescribed in the form of a written schedule which indicated just the kind, amount and times for exercises, baths, rub-downs and rests. The outdoor exercises were regulated "road-work," medicine ball, rope-skipping and sea-bathing. The work in this case was strenuous from the start. Her day was mapped out for her and she lived "by the clock." No attention was paid to the aphonia in the way of formal treatment and no attention was allowed it except by myself when, by persuasion and suggestion, she would be lured away from standing guard over her throat and diverting into allowing it to behave automatically and unconsciously.

Progress was not rapid, but it was sure. It required four months to insure her against recurrence of abnormal dissociations. The latter part of that time was the "hardening" process of monotonously repeated, excitement-free, hum-drum normal life. Since then she has married most happily and has a family of her own. There has never been a recurrence.

This series of 310 cases were grouped as follows:

	Males	Females	Total
Psychasthenia	57	83	140
Neurasthenia	47	80	127
Hysteria	20	23	43
	—	—	—
Total	124	186	310

Thirty of these, nineteen women and eleven men, have been treated by the Training Camp Method, about 10 per cent of the series.

The results have been: 22 cures, 3 excellent, 3 improved, 1 probable cure, 1 treatment not completed. Total, 30.

My experience with it indicates most forcibly the necessity of it *whenever* it can be applied for three reasons especially—1, the permanency of cure; 2, the completeness of cure; 3, the short time required for cure as compared with other methods in similar cases.

DISCUSSION

HAROLD W. WRIGHT, M. D. (Flood Building, San Francisco)—Dr. Orbison's paper indicates that rest is not the only need of the neurasthenic or other type of functional nervous disorder. We are too prone to tell people that they should rest or have a change and leave them unsupervised to dwell on their symptoms and become

more introspective instead of diverting their attention to something objective which at the same time can be used as a method of physical upbuilding. This is particularly of use when the regimen involves doing something competitively after a period of gradual physical upbuilding, e. g., competitive sports and competitive team play. The neurasthenic or other type of neurotic who has become discouraged and diffident and has lost faith in himself as a normally efficient working member of society (and most of these cases are of that sort) requires something to bring back his self-respect and sense of ability to accomplish things. The latter is the reason for any form of occupational therapy. Occupational therapy should not be just a time killer, but should have the elements of interest, physical hardening and zest of accomplishment of something hitherto not believed possible by the patient. While it is true that we cannot afford to neglect mental analysis and the psychological causes of functional nervous disorders so that the patient may learn how to avoid recurrences, it is also of equal importance not to neglect physical re-education and upbuilding and always keep in mind that any patient is a unified personality when well, and has become disharmonized in his entire organism when nervously ill.

As regards the term "neurasthenia," one would hesitate to discard it even though it is often misapplied. It is an accurate descriptive term for those patients who are asthenic following some prior illness of a toxic, infective nature or following prolonged states of anxiety with ensuing disturbance of the functions of the digestive or circulatory or endocrine organs. Perhaps one could criticize the immediate resort to the training camp method in the literal "neurasthenic" until sufficient rest and upbuilding of nutrition had been accomplished by milder methods.

After all is said one must conclude that the personal influence of the physician upon his patient is the most important factor of all in the therapeutic management of such patients.

H. DOUGLAS EATON, M. D. (1136 West Sixth Street, Los Angeles)—In the absence of conclusive facts, theories and theorists flourish. In no realm is this more true than in that of the psychoneuroses. The literature is full of widely differing explanations of the genesis of neurasthenia and its sisters, psychasthenia and hysteria, all of which are as yet unproved. For this reason we are all prone, whatever our specialty, to treat the psychoneuroses and to treat them on the basis of our own pet theory of their etiology and pathology. Is it any wonder that we lose many of our patients to the cultists?

For the above reason it is a pleasure to read Orbison's sane description of these conditions and his clear-cut views as to their therapy. Whatever our views as to the etiology and pathology of the psychoneuroses, certainly present day scientific knowledge demonstrates the value of training in their care and cure.

Before the war, I spent some years working with the psychoneuroses and aided in the development of the so-called re-educational method, now flourishing under Austen Fox Riggs, at Stockbridge, Massachusetts. Our patients were trained mentally and physically. Obviously, one must start with the patient as he is. The malnourished patient needs more rest than exercise, the athlete—and there are neurasthenic, psychasthenic and hysterical athletes—needs more exercise than rest. The objective is the same and eventually we attempt to reach the level of physical and mental normality for that individual. All such training should be founded on the laws of physiology and psychology; the patient's understanding of the method is essential to success or at least to permanent success.

The individual physician's technique, as Dr. Wright suggests, is of great importance, but it is equally important that the technique be founded on a rational conception of the disorders treated.

Orbison's conclusions are in accordance with my own experience in fifteen hundred cases, namely that the psychoneuroses are definite disease conditions without demonstrable pathology; and that approximately 80 per cent go on to cure as the result of physical and mental training administered by competent hands.

MILTON B. LENNON, M. D. (380 Post Street, San Francisco)—As Orbison says, a careful classification of the psychoneuroses is important: We recall years ago when the diagnosis of neurasthenia was as common as it is today relatively rare. The same pertains with psychasthenia. Hysteria, perhaps, is now more frequently recognized than it was a decade ago. With the development of our knowledge, the glandular discrepancies, toxic and infectious conditions, the so-called constitutional inferiorities and mild psychic state, have claimed many patients who formerly were designated as psychasthenic or neurasthenic. It has been the observation of many of us that such classification had better be made with great reserve. A mild manic-depressive state with complete recovery and a later turbulent episode will often point out an error in diagnosis. An early encephalitis may run on for months with all the marks of a neurasthenia, before any defining symptoms supervene. The same can be said of other toxic conditions. These, it is true, can activate a neurasthenia, but the fatigability that they present does not constitute a neurasthenia. The psychoneuroses—if they represent anything—represent definite types of personality. They are an expression of the inherent, inborn nature of given groups of individuals. Under obvious stresses—either mental or physical—symptoms may arise which are distressing, even to incapacity: Others, however, have no such obvious symptoms and can only be reached by careful analysis.

If we bear this in mind we must be very chary of using the term "cure" in any patient with a psychoneurosis; much less can we use the term "permanent cure." Quite plainly can we get rid of distressing symptoms and, perhaps, that is as much as can be asked. The method may be in any of the accredited ways which will do for the happiness and efficiency of the individual.

Doctor Orbison's method is particularly efficacious, since it implies the co-operation of doctor, patient and trainer. It spells out-of-doors, well-regulated exercise and a direction toward healthy habits. It has the advantage of restoring the patient with a laudable degree of rapidity.

The personal equation of the doctor, however, must not be overlooked. Undoubtedly, this has played a large part in the obtaining of such excellent results.

DOCTOR ORBISON (closing)—The discussions of my paper by Doctors Wright, Eaton and Lennon have, in themselves, a remarkably ponderable value—coming, as they do, from neuro-psychiatrists eminently qualified by education and experience to express critical judgments upon the subject under discussion.

In fact they bring out exactly the values of the training camp method and make a better summing up of those values qualitatively than I could expect to do. For example, Dr. Wright has crystallized one whole phase of the subject in a single sentence when he says, "Occupational therapy should not be just a time-killer, but should have the elements of interest, physical hardening and zest of accomplishment of something hitherto not believed possible by the patient."

Again, Doctor Eaton, from a very large experience, is able to state the formulations that: "Obviously one must start with the patient as he is"; we attempt to reach the level of physical and mental normality for that individual. All such training should be founded upon the laws of physiology and psychology, "plus the patient's intelligent co-operation." I know of Doctor Eaton's admirable work at Stockbridge and the notable results obtained.

Doctor Lennon, with his well-known accuracy in analysis, sums up admirably when he says, "The psychoneuroses, if they represent anything, represent definite types of personality. They are an expression of the inherent, inborn nature of given groups of individuals."

I can do no better in closing this discussion than by quoting these careful and experienced neuro-psychiatrists. That they indorse what has seemed to me very simple, but common sense, definite method of treating the psychoneuroses, and concur in its efficacy is very much appreciated, as is the quality of their illuminating discussion.

CORONARY OBSTRUCTION

By JAMES F. CHURCHILL, M. D., San Diego

Sudden obstruction of a coronary vessel is ordinarily due to a thrombus, but an embolus is occasionally found.

Treatment consists in absolute rest in bed, morphin for relief of the pain and the use of digitalis.

Vasodilators are contra-indicated, since there is already a fall in blood pressure.

DISCUSSION by William J. Kerr, San Francisco; F. F. Gundrum, Sacramento; Egerton Crispin, Los Angeles; Franklin R. Nuzum, Santa Barbara.

OBSTRUCTION of the coronary arteries has long been regarded as one of the most serious of cardiac accidents. Indeed, until as recently as 1881 it was considered a fatal one. In that year Cohnheim published his conclusions that the coronaries were end arteries and that occlusion of one of them or one of the larger branches was followed by death within a few moments. This work confirmed that of earlier writers, but did not long remain unchallenged. Numerous workers from 1888 to 1910 published the results of animal experiments, in which death was delayed for some time, and even recovery was noted in a few instances. Clinical observations with necropsy findings also began to be reported during this period, furnishing proof that patients can and do survive for varying lengths of time obstruction of fairly large branches of the coronary vessels.

The object of this review of the subject is to emphasize the relative frequency of coronary occlusion, to point out the variations in the clinical picture, and to discuss some points in differential diagnosis. Immediate recognition and treatment of this condition may, in certain instances, mean much to the patient.

Sudden obstruction of a coronary vessel is ordinarily due to a thrombus, but an embolus is occasionally found. Either artery or any one of their branches may be involved, the most common site being the ramus descendens of the left. That the coronaries are not end arteries, as was formerly taught, was definitely proven by Fred M. Smith, whose excellent work on coronary anastomosis was published in 1918. After infusing the coronary vessels, Smith injected them with a suspension of barium and made stereoscopic films of the hearts, showing in this way not only the presence of actual anastomoses, but also the variation in the size and numbers of these in different hearts.

The result of an obstruction depends upon the size of the vessel affected, the number and size of the anastomoses and the previous pathological state of the myocardium.

In discussing the symptomatology of this affection, one cannot do better than to adopt the classification made by Herrick in his two classical papers on this subject, published in 1912 and 1919.

1. Cases of instantaneous death in which there is no death struggle.

2. Cases with very severe symptoms, usually of typical anginal character, in which death occurs in from a few minutes to a few hours.

3. Cases with symptoms severe enough to be recognized as serious and probably of cardiac origin, in

which death may be delayed for days and recovery eventually occur.

4. A group in which the cardiac symptoms are very mild and in which the diagnosis can only be suspected, or made in retrospect, from the autopsy findings. It is the third group which will be chiefly considered in this paper.

SYMPTOMATOLOGY

The subjects of this affection are those in which angina is commonly encountered that is, men past 50 years of age, though a few verified cases have been reported in the thirties. Those who have had previous anginal attacks will usually describe the seizure as similar, but more severe and more prolonged. The pain may be substernal or radiate to the arms or to the abdomen. Its intensity may be of any degree, though usually very severe.

Symptoms of collapse quickly follow the onset. The pulse is usually weak and rapid and may become irregular, premature systoles being the most common type of arrhythmia. The heart tones are faint, and there is almost always a rapid fall in blood pressure. The face is usually ashen. Profuse perspiration is common. Dyspnoea is not often noted, though it may occur and be accompanied by the appearance of many bubbling rales and the expectoration of frothy, pink sputum, indicative of pulmonary edema. It has been suggested that this edema may occur when the left, and not the right, ventricle is affected.

Nausea and vomiting are not uncommon, and when associated with severe abdominal pain may be very confusing and suggestive of an abdominal condition. Engorgement of the liver and edema of the lower extremities are described, due to a weakened myocardium; but these findings are less common than those mentioned above.

Extreme weakness is the rule, though some patients remain surprisingly strong and may insist upon walking about the room, going to the toilet, etc. The majority of patients prefer to lie flat in bed, but two of my own cases were apparently more comfortable when upright and persisted in sitting in a chair.

A pericardial rub may develop at any time after a few hours, and when found is of great diagnostic importance. It is commonly stated that the mind remains clear almost to the moment of death, and while these patients ordinarily realize the gravity of their condition the fear of death, so commonly described in angina, is noticeably absent.

DIAGNOSIS

The diagnostic points which have led me to suspect coronary occlusion are:

1. Severe persisting pain of anginal type, which is *not* relieved by vasodilators, but only by morphin.
2. Signs of shock as mentioned above, especially the rapid fall in blood pressure.
3. Weakening, irregular heart tones.
4. Pericardial rub.
5. Electrocardiographic findings.

A majority of the reported cases show in the electrocardiogram a sharply negative T wave and a decrease in the amplitude of the QRS group.

Unfortunately, the electrocardiograph is not portable, so that one is not often available as an aid in the diagnosis. However, when the findings above mentioned are obtained, they should be regarded as strongly supporting evidence of coronary obstruction.

DIFFERENTIAL DIAGNOSIS

The two conditions which commonly come in for consideration in the differential diagnosis are uncomplicated angina and acute lesions of the upper abdomen.

The former of these is relatively easy of differentiation, inasmuch as the pain in angina, while it may be as severe, is not so lasting and is usually relieved by nitroglycerin or amyl nitrite. Further, there are not present the marked signs of collapse, especially the weakened heart tones and rapid fall in blood pressure. Of course, those anginal attacks, which are immediately fatal, can only be differentiated at autopsy.

The second group, however, presents many difficulties, and an error may occasionally be unavoidable. Perforation of a gastric or duodenal ulcer, acute pancreatitis, mesenteric thrombosis, and biliary colic may be simulated by a coronary occlusion in every detail for a period of several hours. While the pain in coronary obstruction is more often substernal, it may be referred to the epigastrium, and when to this is added board-like rigidity of the upper abdomen, vomiting and signs of collapse, the patient presents a typical picture of perforation of a hollow viscus. The situation is particularly difficult if there chances to be a former history of digestive disturbances. Differential diagnosis may not be possible for several hours, and it may be necessary to await further developments before a final decision is made. Increasing weakness and rapidity of the heart, or the development of an arrhythmia or a pericardial rub on the one hand, or the appearance of further signs of an abdominal lesion on the other, will usually aid in the differentiation.

As stated before, cases of coronary obstruction show very great variation in their clinical pictures. The following three case histories serve to illustrate and emphasize this fact.

CASE 1—A man of 76 was seen in consultation after having been in intense agony for four hours. There was a history of previous anginal attacks. The pain was substernal, agonizing in character and did not radiate. No relief had been afforded by nitroglycerin, and morphin had been administered with partial, but not complete, relief. The heart tones were feeble. The blood pressure could not be taken on account of the restlessness of the patient. Death occurred about seven hours after the onset. Autopsy showed advanced sclerosis of the coronaries and a soft thrombus in the left main branch. A typical case of the pure anginal type in which a diagnosis may be made with considerable certainty.

CASE 2—A man of 78 who had been very active, a great traveler, and who prided himself on his good health. No history of previous angina or other cardiac symptoms. On the morning of the onset he felt some nausea while at his breakfast. He went at once to his room and vomited a small amount, after which he stated he felt relieved, but not entirely comfortable. There was no pain at this time, however. My associate saw this patient within an hour after the onset. When he entered the room the man set up on the bed to relate his history. At the end of about five minutes he uttered an exclamation, clasped his hands on his abdomen and fell back on the bed. He almost immediately vomited, but

experienced no relief from his intense pain, which he located in the epigastrium. His color became ashen, profuse perspiration appeared, his pulse became rapid and weak. It was learned that, a few months before, his systolic blood pressure had been 145. Four hours after the onset his pressure was 95-60, and he presented the typical picture of shock. While the abdominal pain and rigidity still persisted at this time the signs of cardiac disturbance were so marked that the possibility of a perforated ulcer was dismissed by the surgical consultant and myself. He lived twenty hours from the onset of his severe symptoms. At the end of fourteen hours general weakness was extreme, the heart was very rapid and irregular, and the systolic pressure had fallen to approximately 60, while the abdominal rigidity had disappeared. At the onset this case closely simulated the picture of rupture of a gastric or duodenal ulcer. Although an autopsy was not obtainable, those of us who watched the case felt that coronary obstruction was the only possible diagnosis.

CASE 3—Was a man of 72 who came to the office this winter on account of recurring discomfort under the upper sternum. This had been noted after exercise for about two months and was thought by the patient to be due to "gas." On this account he had developed a marked aerophagia. He was found to have an advanced arteriosclerosis and some increase in the cardiac outlines. The heart tones were clear. The blood pressure was 155-100. He was advised to remain quietly in his room for several days. The second morning after I was asked to see him on account of the same distress. It had come on at about 9 p. m., had been continuous, and he had spent a sleepless night in a chair. The pain was described both as a pressure and a dull pain under the middle third of the sternum; was apparently not very severe and did not radiate. His distress was increased by lying down. On that day the blood pressure was found to be 112-70. His color was grayish and he was in a profuse perspiration. The next morning a faint pericardial rub was heard in the third left interspace near the sternum. His condition remained practically unchanged and relief was only obtained by morphin. On the third day the pressure had dropped to 90-45. The heart was rapid, occasional premature systoles were noted, but there was no change in the heart outlines. He was a very uncontrollable patient and insisted upon going to the bathroom contrary to instructions. He died suddenly on the morning of the fifth day, after returning from the toilet. On the basis of his persistent cardiac pain, pericardial rub, fall in blood pressure, and disturbed rhythm, the diagnosis was made of obstruction of one of the coronary branches. Autopsy could not be obtained.

The point I wish to impress by these three case histories is that there is no single symptom complex typical of coronary thrombus. These three cases present entirely different clinical pictures of what I believe to have been the same pathological lesion.

TREATMENT

The treatment consists in absolute rest in bed, morphin for relief of the pain, and the use of digitalis. Vasodilators are contra-indicated, since there is already a fall in blood pressure. If the patient survives he should be kept in bed over a long period and treated as any other individual with grave myocardial disease.

Electric Building.

DISCUSSION

WILLIAM J. KERR (University of California Hospital, San Francisco)—It has been a pleasure to read Doctor Churchill's paper on "Coronary Obstruction." The description of the symptomatology and physical findings fits in very well with my own experience with this clinical entity. I think all of those who have handled patients with coronary disease have been impressed with the type of pain which the patients describe, being of an anginal type, but persistent and agonizing in character and not relieved by the ordinary vasodilators. Patients who

present the more severe forms of coronary disease, with the associated myocardial changes, give a very striking picture of shock with fall in blood pressure, pallor and profuse sweating. The changes in the heart sounds are also very striking, with marked weakening of the tone of the first sound. The pericardial rub, which Doctor Churchill mentions, is not very frequently observed, but quite a percentage of cases show at necropsy pericardial involvement. Electrocardiograph findings are not constant, but usually show evidence of disturbance of the conduction system in the ventricles and abnormal T waves. The gastro-intestinal symptoms may be very prominent and suggest conditions in the abdomen of a very severe type and may even result in surgical measures, which naturally are of no value and may result fatally.

It was of interest to review the pathological findings in such cases and to learn that many patients show evidence of previous coronary occlusion with fibrosis of heart muscle resulting from this occlusion. This is ample evidence that patients may go through mild attacks of coronary occlusion and recover in many instances without having experienced any symptoms in the past history which would lead one to make such a diagnosis.

I quite agree with Churchill in regard to the treatment in these cases. Rest is the most important single factor with relief from pain by the use of opiates. A long period of rest is absolutely indicated. There is great danger of embolism as a result of mural thrombosis.

F. F. GUNDRUM, M. D. (Capital National Bank Building, Sacramento)—Doctor Churchill's paper brings back to our attention a medical accident which, though not extremely common, is, nevertheless, possibly considerably less rare than we ordinarily suppose. It is not always met with in old men, but may occur in women, and even in comparatively young women. I have attended a woman who died of coronary occlusion at the age of 42. The diagnosis was confirmed by autopsy. The source of the thrombus was not determined. It is of first importance that coronary occlusion be not mistaken for some of the acute surgical accidents of the upper abdomen. This mistake is less apt to occur if opportunity for a case history presents itself. The history taking may be difficult at a time when the patient is extremely uncomfortable and sick and the family much excited and anxious. Hasty surgery has here such melancholy results, however, that time spent upon a thorough investigation into the patient's previous health is well spent. There is also very rarely a true muscle spasm of the abdominal wall, which is so frequently present after perforation of a viscus high up in the abdomen. I agree with Churchill that there are possibly more sufferers from coronary occlusion than are so diagnosed and particularly there are a fair number whose lesion is sufficiently limited that they recover to a fair amount of activity for a time.

EGERTON CRISPIN, M. D. (Pacific Mutual Building, Los Angeles)—Doctor Churchill's paper is a well prepared presentation of a subject that must frequently be brought before the profession in order than anginal symptoms may be more often clinically segregated into relationship with the probable pathologic origin. The established proof that coronary arteries are not end arteries, the recent clinical observations of the surgeons, after cutting the superior cardiac nerve for the relief of spasmodic type of anginal pains, and the correlation of careful autopsy findings with the clinical observations of pain attacks, have helped in gathering together a group of symptoms that strongly suggest coronary obstruction as their cause.

Nearly all observers agree in the main symptoms; particularly the prolonged type of pain; falling pressure; absence of relief from vaso-dilators and the need for morphia. The type of person in whom the attack occurs and the probability of sclerosis in the aorta and in the coronaries, help in suggesting the possible origin of pain. More frequently will the type of pain from coronary involvement occur in epigastrium. Where it occurs sub-sternal the radiation to extremities is less often present. The person with spasmodic type of angina may be gravely ill while under the strain of the fear, or emotion, or anger, that brought on the attack, but feel quite himself the next day. The patient with pain from coronary obstruction is an ill man for whom effort must

be suspended. The infarct or fibrosis may only be put to test with caution until myocardial integrity has been established at effort levels.

Rather typical of the obstructions in group classed as Number 3 by Doctor Churchill, is that these folks may have comparative comfort when effort is within myocardial circulatory limits, and how sure distress comes when these limits are exceeded. With this in mind and impressed upon patients having had symptoms of obstruction, possibly to some extent attacks may be averted. Comparatively one effort level might be cared for with the limited blood of a partially occluded vessel, but all symptoms of obstruction develop if increased effort made demands on coronaries that could not be supplied. This borne in mind may permit some patients with this disease to live longer with some comfort.

FRANKLIN R. NUZUM, M. D. (Santa Barbara)—A complication of coronary obstruction not mentioned in Doctor Churchill's excellent paper is rupture of the heart. This accident has been considered as of rare occurrence, but in certain types of service, such as coroners' examinations and in insane asylums, frequent instances of ruptured heart wall are coming to light. They are noted particularly in coroners' services because sudden death follows the rupture. They are noted in insane asylums because the life of such an individual tends toward the pathologic processes which are found in coronary obstruction and infarction of the myocardium.

I have had personal experience with five instances of ruptured heart, three of which occurred in general hospital practice. The pathology back of each of these instances, and back of some 250 instances that I have found in the literature, is primarily an occlusion of one of the large branches of either the right or left coronary artery, resulting in infarction of the muscle wall. By far the large majority of instances have occurred in the anterior wall of the left ventricle at or near the apex. This area is supplied by the descending branch of the left coronary artery, and an occlusion of this branch or of the arteries supplying the affected area is found when carefully looked for. Rupture of the heart never occurs in a normal muscle wall, and likewise rupture through an old healed infarct has not been recorded.

Death usually follows shortly after the rupture, so that therapy is not of avail, but in going over the history, occasionally a diagnosis of a former occlusion of a coronary artery can be determined. In some instances this preceded by days or weeks the rupture of the heart wall.

Many instances of rupture of the heart wall undoubtedly occur in general hospital practice, which at present are not being diagnosed. A familiarity with the subject of coronary occlusion and an increasing desire on the part of physicians to obtain post mortem examinations routinely will bring to light many such examples.

The importance of absolute rest at the time the diagnosis of coronary occlusion is made, as suggested by Churchill, is most important in preventing rupture of the area of myomalacia cordis, which follows the infarction.

The Spinal Fluid in the New-born, With Especial References to Intracranial Hemorrhages—A study of the spinal fluid of 423 new-born negroes was made by M. Hines Roberts, Atlanta, Georgia (Journal A. M. A.). Each of these fluids contained a yellow pigment, bilirubin, which persisted at least until the ninth day, and was intensified if jaundice occurred. It cleared by the fourth week. The intensity of pigmentation was closely related to the physical development of the infant. Sixty cases, or 14.1 per cent, showed the presence of intracranial hemorrhage, two due to hemorrhagic disease, and fifty-eight to trauma. Abnormal labors or operative procedures tend to increase the incidence of intracranial hemorrhage. Prematurity is a definite etiologic factor. Only twenty-six of the sixty cases presented symptoms attributable to intracranial hemorrhage. Fifty-four of the sixty children have been followed; twelve are dead, ten because of hemorrhage, two as the result of some intercurrent infection. Forty-two children are known to be alive, only two of whom show symptoms due to hemorrhage. The remaining forty seem perfectly normal.

TUBERCULOSIS OF THE SEMINAL TRACT

(From the Department of Urology, Stanford University Medical School)

By JAMES R. DILLON, M. D., San Francisco

The only hope of radical cure or complete arrestation of the disease is by the radical operation—that is, excision of the tuberculous seminal tract.

If the patient with unilateral epididymitis is seen early enough there may be hope of removing the entire tuberculous tract while it is still limited to one side, and saving for him the opposite seminal tract.

DISCUSSION by Martin Molony, San Francisco; R. L. Schulz, Los Angeles; Floyd F. Hatch, Salt Lake City.

GENITAL TUBERCULOSIS is such a progressive affection, that any method, however radical, which offers a better chance of recovery is worth serious consideration. At the present time conservative treatment by epididymectomy holds the majority opinion because of the generally accepted belief that the primary focus is in the epididymis and that from this the disease quickly spreads to involve the vesicle and prostate, and by removing the epididymis or testicle the secondary focus will subside and improve the chances for the escape of the opposite side. That such a result is not always obtained and that our attempts to cure genital tuberculosis by epididymectomy leave much to be desired is shown by the published statistics of many urologists.

Barney reported the end results of seventy-one cases, stating that of sixty-nine operated on, but twenty-six were seen after unilateral epididymectomy without involvement of the opposite side; twenty-three returned with infection of the second epididymis, and twenty were examined after bilateral operations. Young reports, out of sixty-three patients, only twenty-seven are known to be or have been alive three years or more since admission. Eighteen were not heard from. He further states that the urinary tract was not involved in thirty-nine cases and as these were fairly early cases of tuberculosis of the seminal tract, the result obtained by epididymectomy or castration were very poor. Keyes reported relapse in fifty-three out of eighty-seven cases. The last six years at the Mayo clinic, Hunt reports forty-two out of sixty-six cases having bilateral disease; (twenty-four were bilateral on admittance, sixteen unilateral operations elsewhere and two have since developed opposite epididymitis). Barney reported definite involvement of the prostate and seminal vesicles in seventy-six out of one hundred and one cases examined. Hunt reported fifteen out of sixty-six, and Young 61 per cent bilateral seminal vesiculitis. Keyes states that every case carefully examined showed some congestion of the internal genitals, which he thinks is always tubercular, hence believes that tubercular epididymitis is always an index of general T. B. of the genital organs.

The various interpretations of digital examinations by different urologists offers a very unreliable basis for deciding the primary focus whether in the epididymis or in the upper genital organs, where practically all clinicians admit tuberculosis may be present, but impossible to detect, though the tubercular epididymis is definite. Also the autopsy records cannot offer complete proof because in the

vast majority of cases, by the time the patient dies, the genital tuberculosis is so extensive that its exact origin is entirely obscured. There are a few isolated cases reported in which only the epididymis, seminal vesicle or prostate were diseased, but the number is too small to draw conclusions from.

Though but fifty-four radical operations have been published in the American literature, forty-four of these having been done through the perineum by Whiteside, Young and Quinby, one cannot help but be impressed by the consistency in these reports of the extensive involvement of the seminal vesicles and vasa. The inadequacy of epididymo-vasectomy in the majority of cases of seminal tuberculosis was particularly impressed on me a few years ago by following four successive cases from unilateral epididymitis, to bilateral, then to prostatic and bladder symptoms, with perineal abscesses and fistulae in one and active pulmonary tuberculosis started in the other three.

The early methods of dealing with the condition was by complete castration. This procedure has been justly condemned, except when the testis is extensively diseased. A further step was taken by Barney and Cabot in removing most of the vas by making an additional small inguinal incision and pulling the vas up from the pelvis, leaving only the upper third of the vas. In 1918 Young presented a simplified technique for the entire excision of the seminal tract through scrotal and perineal prostatectomy incisions. In 1922 he reported fifteen cases, operated on during a period of seven years, "(in some of which the lungs were probably previously involved, and in five of which one kidney was tuberculous) and in which only one patient died of tuberculosis a year later, and the others are apparently completely arrested, shows the effectiveness of this radical operation." Quinby reported seven cases in 1918, which were followed for an average time of thirteen months and showed "an apparent return to complete health." None of his cases, however, "showed signs of active tuberculosis elsewhere in the body." In 1914 Whiteside reported twenty-two cases of radical operations which he had employed in "only the old and apparently hopeless cases," with a high mortality. In 1919 he reported more gratifying results "in several cases," but advised against radical operation in the presence of active pulmonary tuberculosis.

It is admitted that all the tuberculous process is not removed by epididymectomy and as long as tuberculous diseased organs are left, as the vas, vesicles and prostate, we have not reached a satisfactory solution of our problem. This is further proven by Barney's report on 113 cases operated on by epididymectomy and traced from one to twenty-five years in which 27 per cent died of tuberculosis. Of fifty-eight of these dying in the first six years, 41 per cent died of tuberculosis.

As Quinby states, "it may not be the opportunity of any of us to bring together an amount of operative material sufficient for complete proof, nevertheless, the continued efforts of many of us will bring the answer," and to that end I am presenting my series of cases.

CASE 1. J. E. McK., age 33, American, San Francisco Hospital. No. 54695. Aug. 20, 1921. Complaint:

Swollen testicle. Post History: Gonorrhea 1908, chancre 1918, dry cough for many years, constipation 2 years, "bleeding piles" for 6 years. Hard lump in right testicle for 8 years with pain in groin. For past 6 months has had discharge from testicle.

Present Illness—Right testicle swollen and painful, last few weeks sinuses discharging more. Examination: Thin man in distress. Aug. 26, 1921, chest exam. (Dr. W. R. P. Clark) slight old T. B. lesion right apex. No activity noted. Fleuroscopic negative. Heart and abdomen negative. Right epididymis enlarged, irregular and hard with two small discharging sinuses; right testis also hard and nodular; right vas thickened and granular. Left testicle and vas normal. Prostate granular consistency, indurated toward base; both vesicles infiltrated and enlarged. Cystoscopic examination Aug. 23, 1921: Bladder wall and ureteral orifices appeared normal; ureters easily catheterized; urine from kidneys and bladder was clear, but G. P. reported positive Oct. 14, 1921. Function normal.

Diagnosis—T. B. epididymitis, right; T. B. prostatitis and vesiculitis.

Operation—Sept. 30, 1921. Nitrous oxide and oxygen-ether anesthetic. Double vesiculectomy; varumontanum was caseous and came away with vesicles, leaving a hole in the urethra allowing urine to escape; artial prostatectomy; right vasectomy; removed ampulla of left vas; right epididymectomy; resected right testis. Suprapubic cystotomy done because of opening in prostatic urethra.

Pathology—Tuberculous right epididymitis, deferentitis and vesiculitis also left seminal vesicle and left ampulla.—(F. E. Blaisdell.)

Oct. 15, 1921, complained of pain in left testicle; examination showed small nodule size of pea in lower pole. Oct. 18, 1921, operation, left epididymectomy and vasectomy under local and gas and oxygen.

Pathology—Tuberculosis lower pole epididymis and tuberculous deferentitis. (Further study of the left ampulla removed at the first operation showed tuberculosis throughout the length removed through the perineum, though there was no clinical evidence at that time in the cord or testicle.)

Nov. 18, 1921. He left the hospital against advice. Had been given tuberculin for a month previous and was in good condition, except for a slight discharging perineal sinus, which closed soon after. He was seen two months ago and stated he had been cystoscoped by Major Fox of the Letterman General Hospital and told there was no T. B. left, and that Guinea pigs inoculated with the urine were negative. He is perfectly well and gained from 105 to 125 pounds in weight.

CASE 2. D. P., Mexican, age 29. San Francisco Hospital No. 66878, May 4, 1923.

Complaint—Swelling and pain in left testicle.

Past History—Three gonorrheal infections, 10 years, 3 years and 5 months previous. Cough with yellow expectoration and loss of twenty-five pounds in last year; shortness of breath for one year; hemoptysis twice six months ago. Night sweats for one month.

Present Illness—Started with acute gonorrhea five months previous; apparently cured in one month; two months ago left testicle swelled; subsided in two weeks and returned to work; swelled again one week ago and is very painful. Examination—Emaciated; harsh and moist rales at apices and right base. Increased vocal fremitus. Fleuroscopic examination of chest: Broncho bilateral pulmonary T. B., both lungs (Dr. W. R. P. Clark); heart and abdomen negative; right epididymis and testis normal; left epididymis greatly enlarged, nodular and fluctuant. Testis apparently normal; prostate showed hard nodule at left base; left vesicle greatly distended and fluctuant (three or four times normal size); right vesicular region and prostatic lobe felt normal to palpation. Urine negative, except for a few pus cells. Wasserman xxx. Sputum positive for T. B.

Diagnosis—Chronic suppurative epididymitis and vesiculitis tubercular. Pulmonary tuberculosis. Syphilis.

Operation May 10, 1923. Double vesiculectomy under spinal anaesthesia (Tropococaine 2 grains). Left vasectomy and epididymectomy, using a few cc. of 1 per cent Novocaine locally to finish.

Pathological Report—Left seminal vesiculitis tuberculous; right seminal vesicle, normal; left epididymitis,

Case 1.—Tuberculous Right Seminal Tract and Left Vesicle and Ampulla. (Left Epididymis and Vas Clinically Normal.)

Case 2.—Tuberculous Left Seminal Tract. (Right Seminal Vesicle and Ampulla Normal.)
Case 3.—Both Seminal Tracts Tuberculous Throughout.

tuberculous; left deferentitis, tuberculous.—(Dr. F. E. Blaisdell.)

June 15, 1923. Has improved and gained some weight. Perineal wound healed, but scrotal sinus draining. Transferred to T. B. Hospital.

June 26, 1923. Bleeding freely from nose. Hemoptysis at times, considerable cough. Pulmonary condition grew progressively worse and he died August 17, 1923, four months after operation.

CASE 3. L. P. Private case. Italian, Age 30, March 23, 1923.

Complaint—Swollen testicles. Past history: Occasional stomach attacks; gonorrhea 7 years previously.

Present Illness—Started four or five months ago with frequency of urination; three months ago left testicle swelled; two months ago right one swelled. Slight pain. Examination: Impotent for several months. Suppurative orchitis and epididymitis left testicle; right epididymitis with abscess; thickened and indurated vasa; left seminal vesicle thickened and sclerosed; right seminal vesicle thickened, larger but more fluctuant than left; prostate nodular. Cystoscopic Examination: Kidneys catheterized and found apparently normal. Marked trigonitis and congestion of bladder mucosa over vesicular regions; congested prostatic urethra. No evidence of active pulmonary lesion. Heart and abdomen negative.

Diagnosis—Left tubercular orchitis, epididymitis, deferentitis, vesiculitis; right epididymitis, deferentitis, vesiculitis; tuberculous prostatitis and trigonitis.

Operation—April 16, 1923, at St. Francis Hospital. Double vesiculectomy and partial prostatectomy; double vasectomy; left orchidectomy; right epididymectomy.

Pathological Report—Tuberculous orchitis, epididymitis, vesiculitis and deferentitis.—(Dr. F. E. Blaisdell.)

Discharged from the hospital May 5, 1923, with a small perineal sinus discharging a little pus. Improved greatly in health and gained weight until "stomach" began to bother him four months later which was treated by his family doctor. Cystoscoped Sept. 20, 1923, and kidneys found normal. Operated on by Dr. J. F. Cowan for ruptured gall bladder Sept. 23, 1923, and died next day. No evidence seen at operation of tuberculosis

of peritoneum or abdominal viscera as far as could be inspected.

Pathological Report on Gall Bladder—Chronic Cholecystitis with perforation. No evidence of tuberculosis in sections examined.—(Dr. F. E. Blaisdell.)

CASE 4. J. V. Private case, American, age 34. Stanford University Hospital Record 34703. Complaint: Abscess in left groin.

Past History—Always well until one year previously, left testicle swelled without apparent cause. Castration done, but permanent sinus persisted, opening and closing at times with abscess formation. Examination: Small abscess in left inguinal region. Left testicle absent. Right testicle normal. Prostate and right vesicular regions normal. Left seminal vesicle and vas greatly thickened and indurated. Urine clear with few pus cells in centrifuged sediment. No acid-fast bacilli seen. No active pulmonary lesions. Heart and abdomen negative.

Diagnosis—Left T. B. vesiculitis and deferentitis. Treatment: Incised abscess and drained ten days. Nov. 21, 1923: Left vesiculectomy and vasectomy through perineal and inguinal incisions. Dec 8, 1923, wound healed.

Pathological Report—Chronic tuberculous vesiculitis and deferentitis.—(Dr. F. E. Blaisdell.)

This patient was seen one month ago, "feeling fine and gained twenty pounds since the operation."

CASE 5. S. G., Greek, age 29. Private case of Dr. A. Roncovieri (Industrial Accident), Feb. 12, 1924.

Complaint—Pain in right groin.

Past History—Epididymectomy two years previously; questionable tuberculosis.

Present History—Felt all right until an injury four months ago, followed by a hernia in the right side. Right inguinal herniotomy done three months ago. Six weeks ago right testis became inflamed, abscessed and was removed. Sinus in scrotum still draining.

Examination—Tender hard mass in right inguinal region, extending from upper part of scrotum into inguinal canal. Rectal examination shows the right seminal vesicle and vas markedly tender and infiltrated to the size of two fingers. Left testicle, cord, left seminal vesicle,

and prostate normal palpation. Cystoscopic Examination: Kidneys, bladder and urine normal.

Diagnosis—Tuberculous, right deferentitis and right vesiculitis.

Operation at Stanford University Hospital Feb. 14, 1924. Right vasectomy and right vesiculectomy through inguinal and perineal prostatectomy incisions.

Pathological Report—Tuberculous seminal vesiculitis and deferentitis.—(Dr. F. E. Blaisdell.)

March 6, 1924, Dismissed from hospital. March 21, 1924, sinus healed.

April 24, 1924, last examination. No evidence of involvement of left side. Patient gained weight and been working a month on a ranch.

Considering the microscopical pathology, we find complete and total destruction of the entire intrinsic structure of the seminal vesicle and ampulla of the vas on the side of the epididymitis. The mid portion of the vas showed the least destruction, generally a cellular infiltration with scattered giant cells and an occasional area of caseation. The lesion in the lower portion next to the epididymis was as extensive as the ampulla generally. The lower pole of the epididymis was the most frequently involved, showing generally complete destruction, while the upper and mid parts presented many normal areas.

In case 1 the left epididymitis was certainly secondary to the vesiculitis and infection of the left ampulla as shown by the development of the epididymitis two weeks after the diseased vesicle and ampulla were removed, leaving the upper end of the vas still containing T. B. lesions. Also the first appearance of the infection in the lower pole is fairly conclusive evidence of the extension from the central organs by the lymphatics down the cord.

In case 2 the left vesicular lesion was just as destructive as the epididymal, though the epididymitis was but two months old, also the upper and lower ends of the vas were extensively involved, while the upper pole of the epididymis showed normal areas. His right seminal vesicle and ampulla were microscopically normal and even though he died of extensive pulmonary tuberculosis four months later, the right epididymis and vas remained normal, again showing the strong probability of primary vesicular infection.

Case 3 shows conclusively primary prostate and vesicular infection by the epididymitis being preceded by a month or two of bladder neck symptoms with normal kidneys before and after the perineal operation.

Cases 4 and 5 prove that all cases of tuberculous deferentitis and vesiculitis do not abate on epididymectomy or castration, and speak conclusively for the early radical operation.

Tuberculin was used for relatively short periods of time in the first three cases and was undoubtedly effective. Directions in general T. B. hygiene were given in all cases. Spinal and local anaesthesia worked very well in the second case and should be used in all cases of doubtful pulmonary conditions. Sterility should not enter the question of doing the radical operation, as practically all cases of tuberculous epididymitis, whether unilateral or bilateral, are reported as sterile (another point showing the primary, or very early involvement of the vesicles or vasa). As to impotence, the first and third cases were so before the operation, while the fourth and fifth unilateral cases were not materially affected.

Case 5.—Tuberculous Right Seminal Vesiculitis and Deferentitis.

The first patient has recovered his sexual capacity to a satisfactory degree. Though too short a time has elapsed since the operations to draw conclusions as to recurrence of tuberculosis in them, certainly a more hopeful outlook is given them by the more complete removal of diseased organs.

CONCLUSIONS

The above case reports, operative findings, and pathological examinations indicate the probable primary tuberculous lesion of the seminal tract to be most often in the pelvic genital organs.

The globus minor of the epididymis is generally next attacked.

The only hope of radical cure or complete arrestation of the disease is by the radical operation—that is, excision of the tuberculous seminal tract.

A better educated examining finger will detect more involvement of the prostate and vesicles.

If the patient with unilateral epididymitis is seen early enough there may be hope of removing the entire tuberculous tract while it is still limited to one side, and saving for him the opposite seminal tract.

(I wish to express my appreciation of the kind assistance given me by Doctor F. E. Blaisdell in photographing the excised organs and in studying the pathology.)

490 Post Street.

DISCUSSION

MARTIN MOLONY, M. D. (1054 Sutter Street, San Francisco)—Doctor Dillon is to be congratulated on bringing forward the question of the cure or arrest of genital tuberculosis by radical operation. This subject has been the cause of much discussion with production of numerous statistics. A correct knowledge of the disease: How it originates and how it spreads, is the first essential to a successful attempt at extirpation.

Tubercle bacilli do not always indicate their presence by the production of a tuberculous lesion: moreover tracing the paths taken by tuberculous infection when it has gained entrance into the body is especially difficult.

To treat tuberculosis of the epididymis or any other

portion of the uro-genital tract as if it were a separate pathological entity would be entirely irrational. Tuberculosis of the testicle is, in the great majority of cases, but an indication of disease in the uro-genital tract at large and showing a tendency to become generalized. Any separation of uro-genital tuberculosis into anatomical divisions is artificial and merely for convenience sake. Tuberculosis of the testicle or any portion of the uro-genital tract is almost always secondary to tuberculosis of the lungs or lymphatic glands and is rarely the sole manifestation of tuberculosis in the body. Tuberculosis of the epididymis is rarely the primary lesion in the uro-genital tract: Infection of the testicle takes place in tuberculosis as in gonorrhea by means of the cord and not by the blood stream. It is extremely rare to find tuberculosis of the epididymis without finding some indication of disease of the prostate or vesicles. Prostatic tuberculosis, on the contrary, is frequently found without any lesion in the testicle.

Tuberculous disease of the testicle is analogous to acute infections extending to the urethra, tuberculous epididymitis has no analogy to the haemotogenous orchitis of mumps. The prostate, therefore, with its surrounding network of lymphatics, plays an extremely important role in the development of tuberculosis of the testicle. It is the market square for distributing tuberculosis to the seminal vesicles and testicle just as it distributes gonococcal and pyogenic infections. Post-mortem statistics and laboratory experiments show that such is the case. Tuberculosis of the genitals is found very commonly associated with tuberculosis of the kidney. When nephrectomy is successfully performed in those cases of uni-lateral tuberculosis of the kidney, improvement in the genital disease invariably follows. Removal of the epididymis, prostate and vesicles is a severe operation and may have serious consequences upon the general condition of a patient with tubercular disease. The field of operation is liable to be flooded with tubercle bacilli and we know instances where rapid tuberculosis followed operation resulting in the death of the patient.

The removal of a tubercular tonsil in a case of renal tuberculosis produced an acute exacerbation of the renal disease and death followed. Radical operation on a rectal fistula produced an acute outbreak of tuberculosis of the lungs with death. Many instances can be cited where extension of the tuberculosis followed operative procedures.

Heroic operations for the removal of genital tuberculosis have not given satisfactory results and have been abandoned by most surgeons.

Genital tuberculosis is a comparatively mild form of tuberculosis and is not of itself dangerous to life. The chief danger is involvement of the urinary organs. Dietetic, hygienic and tuberculin treatments are often successful. Surgery should be limited to drainage and treatment of abscesses and sinuses.

R. L. SCHULZ, M. D. (Story Building, Los Angeles)—Different tissues present different degrees of susceptibility and regeneration following infection with the tubercle bacillus.

We know that tuberculosis of the kidney is not arrested until complete destruction of the kidney has taken place. The ureter and bladder become involved secondarily and if the lesions have not become too extensive, healing takes place after the source of infection in the kidney has been removed. The reactions to tuberculosis differ in kidney on the one hand and in the ureter and bladder on the other. The kidney is composed of a soft, richly cellular epithelial tissue with comparatively little connective tissue, its resistance to tuberculous ulceration is practically nil. The ureter and bladder are composed chiefly of connective tissue in which the resistance to tubercle infection and tendency to repair is good. There is also a good tendency toward repair of tuberculosis in bony and lung tissue, if the lesion has not become too extensive and if the proper hygiene is followed.

A similar condition exists in the genital tract. The seminal vesicle and epididymis have no resistance to tubercle infection. The vas seems to have better resistance, the lesions are not so extensive in the earlier stage. The vas seems to react something like the ureter in regard to tuberculosis. The relative proportion of epi-

thelial tissue in the seminal vesicles and epididymis is greater than in the vas or ureter. Perhaps it is because of this that these tissues are more susceptible. At any rate, we know that spontaneous healing of these organs does not occur without their complete destruction as in the kidney and there is greater probability of extension of the process to neighboring tissues.

From this point of view, the principles upon which this operation is based are fundamentally correct and any procedure less than that cannot be expected to result in a cure. The radical operation removes those portions that are diseased and not capable of spontaneous healing. Thus it gives the other organs, whose resistance is better, a chance to recover.

It is important to consider the general physical condition of the patient, particularly with reference to tuberculosis elsewhere, kidneys, lungs and bones. We should not be arbitrary, but by careful observation determine if the patient has sufficient vitality to recover after a radical operation or whether the progress is so rapid that recovery is not to be expected. I would consider the slowly progressive cases, otherwise in good physical condition, more suited for this operation, particularly where there is good tendency toward fibrosis of the tissues.

If a patient's general condition is such that he could not stand the radical operation, epididymectomy and implantation of the free end of the vas into the skin of the inguinal region so as to provide drainage might be tried. I have seen wonderful improvement in an otherwise hopeless case where the vas was drained for a long time. If the patient's general condition can be improved, the radical operation can be done with greater safety.

FLOYD F. HATCH, M. D. (Deseret Bank Bldg., Salt Lake City, Utah)—It is my opinion that radical removal of large portions of the genital tract in cases of local tubercular infections of the tract is not wholly justifiable except in certain instances. The patients are often in poor physical condition, the operative mortality is high and statistics show that a reasonably large percentage recover with operations of a palliative nature, when accompanied by proper general tuberculosis regime.

As genital tuberculosis is frequently but a local manifestation of a general tubercular infection, a remnant left in the genital tract does not of necessity do every patient positive harm; while a formidable operation may so reduce vitality as to make the patient an easy prey to generalized tuberculosis or a secondary infection.

I consider the radical operation suitable only in cases where recovery does not follow persistent and conservative medical and surgical treatment.

Doctor Dillon's carefully prepared data will add to the accumulating fund of reliable information and aid us in more clearly defining the justifiable attitude in treatment of tuberculosis of the genital tract.

Doctor Dillon (closing)—I feel very grateful to Doctors Molony, Schulz and Hatch for their very able and valuable discussions which cover practically all the important points on the treatment and management of seminal tuberculosis. It is quite true that genital tuberculosis is a secondary infection, but in a large number of cases there are no demonstrable primary foci. If we can develop an operation which will completely remove the entire secondary genital focus, consisting of chronic abscesses of the vesicles in most cases, we can offer those patients a better chance for a complete cure of their primary focus and a longer lease of life, under proper anti-tubercular hygiene.

The chief handicap to a more widespread use of the radical operation is the difficulty of the operative technique. Perineal surgery is attended by a relatively low operative mortality record, and in trained hands operative accidents are becoming rare, so that the surgeon is gaining more confidence in his ability to save and prolong lives with a minimum risk of bad functional results.

"The real master," says J. E. Sweet in an interesting definition of research (Ohio Med. Jour.), is the man who has the proper balance between science and art, the man who really knows what constitutes medical research. Medical research is composed of only two things—a point of view and time to think."

THE IMPORTANCE OF PROGNOSIS IN SOME ACUTE ABDOMINAL SURGICAL CONDITIONS *

By R. E. SKEEL, M. D., Los Angeles

Prognosis under various forms of surgical treatment is of great importance to the patient and the surgeon, but of more importance to the patient is the prognosis if no operation is performed—what will be the outcome and what can he expect before a natural termination is effected either by cure, permanent disability or death?

The surgeon's satisfaction over a technically accurate and perfectly completed operative manipulation is not likely to be shared by the patient's friends or the public at large if the patient dies, and it behooves us always to look beyond the general diagnosis and its implication of an operation, to the question of prognosis in which it has well been said that experience is fallacious and judgment difficult.

As prognosis depends upon a minute differential diagnosis, anything which contributes to an accurate pathological diagnosis contributes likewise to an accurate prognosis and here lies one of the drawbacks in the otherwise excellent movement known as hospital standardization. It is unfortunate that some term other than "standard" was not devised to meet this hospital reform movement, for standardization means standing still on our present knowledge, the limitations of which we all acknowledge.

THE short paper which I have the honor of presenting to you is a plea for greater consideration of prognosis in certain acute surgical diseases, prognosis in this connection meaning the course and natural termination of the disease without treatment other than nature provides.

Medical literature abounds in the consideration of disease processes under the headings of etiology, pathology, symptoms and diagnosis, prognosis and treatment. Hints or statements regarding prognosis are often found under other headings, but when discussed separately writers frequently deal with prognosis as influenced by various forms of treatment, not the uninterfered with natural termination of the disease process.

Prognosis under various forms of surgical treatment is of great importance to the patient and the surgeon, but of more importance to the patient is the prognosis if no operation is performed. What will be the outcome and what can he expect before a natural termination is effected either by cure, permanent disability or death? Together with the prognosis under surgical treatment, this is what the patient must know before he decides between letting nature take her course or submitting to operative procedures, for after all it is the patient who must decide, unless by specific request he passes to the surgeon the responsibility of decision. In this connection, one always recalls Kocher's famous dictum when discussing the subject of "Gall-stones: Do They Belong to the Physician or the Surgeon?" Kocher's answer was that they belonged to neither; they belonged to the patient, and if he chose to drink Carlsbad water and keep his gall-stones it was no one's business but his own.

It is axiomatic that no prognosis can be given until a diagnosis is made, but with present-day facilities a *general* diagnosis is almost always possible, while prognosis tarries far in the rear because

a more minute pathological diagnosis is not at hand. Operative procedures are likely to be advised on the basis of this *general* diagnosis alone, whereas, excepting only such conditions as carcinoma, intestinal strangulation and visceral perforation, they should be advised on the basis of the prognosis in the *individual* case, and in this connection it is interesting to observe that our advice is likely to be based on the absence rather than the presence of prognostic knowledge, as illustrated by the following examples:

ACUTE APPENDICITIS

Even in an audience composed of a distinguished aggregation of surgeons, how many know the prognosis of absolutely untreated appendicitis? A surgeon of vast experience and more than local reputation, in a personal conversation, made the positive assertion that every one of his operated patients with acute appendicitis would have died had they not been operated upon, that the conditions revealed when the abdomen was opened proved that a fatality was imminent and recovery impossible. When this man said to his patient with acute appendicitis that he must submit to operation or die, he was perfectly honest but profoundly mistaken. The opinion was in error, inasmuch as it was based solely on operated patients, since he did a referred practice and never knew how many recovered spontaneously or under some form of expectant treatment.

Twenty-five years ago I was proud of the fact that I had only a 15 per cent death rate in a fair series of operated patients with acute appendicitis, but this mortality was based on neglected, delayed cases; all, either with general peritonitis or localized abscess, which had not yet ruptured into the intestine. In other words, there was a salvaging of most of the 85 per cent instead of a loss of 15 per cent, but even some of these conceivably could have recovered without operation.

At this time I was much intrigued by acute appendicitis, for the early operation was not favored by all surgeons and was decidedly opposed by most physicians, so I pounced with avidity upon a hospital report issued by one of the smaller Vienna institutions that accepted male patients only, and in which operation for acute appendicitis never was performed. I came upon this report by accident while browsing around the library of the old Krankenhaus, and it showed a mortality rate for acute appendicitis, unoperated, of exactly zero. Like many other things European, however, there had crept into these statistics a trifling sophistry, for there had been exactly fifteen deaths from acute peritonitis in men. Allowing that one or two of these were perforating peptic ulcers, it seems rational to think that 15 per cent might be a fair prognostic rate to put upon acute appendicitis, without operation, but even this seems extravagantly high when one considers the great number of patients reporting one, two, or three previous attacks of appendicitis from which they had recovered. As a matter of fact, we don't know the spontaneous death rate of uninterfered with appendicitis, nor have we as yet any exact data to guide us in the individual case with which we may be confronted. In early cases, therefore, we advise operation, because of the practically uniform

* Presented at the General Sessions of the C. M. A. at the Yosemite meeting, May, 1925.

recovery rate and our ignorance of what will happen if operation is done. There are other weighty reasons, such as cutting short the period of pain and disability and the removal of the diseased organ, but, on the whole, if operation presented more deaths than a let-alone policy, the patient might be quite willing to suffer longer and carry his potential assassin in his abdomen.

TUBAL PREGNANCY

What is the prognosis of tubal pregnancy? How many surgeons ever have seen a death from tubal pregnancy if no operation was performed? I suppose that all coroner's physicians in large cities have seen some instances, but I have not.

Of course, we understand that an explanation is found in that even the most rabid anti-medical faddist relents at the last moment and calls medical or surgical aid, so that operation is done on most patients before death ensues—but just how often would death ensue? That some die is certain, but a prognosis, based on the old idea that a large vessel is bleeding and must be tied, else the patient will die, is entirely fallacious. That rupture of a tube at the uterine horn might cause sudden death from hemorrhage is conceivable, that tubal abortion would have the same result is equally conceivable and that death might follow repeated chorionic erosion through the tubal peritoneum, if the foetus lived, is quite possible. All patients with sudden hemorrhage into the closed abdomen suffer as much from peritoneal shock as from blood loss, just as patients with duodenal or gastric perforation suffer shock from extravasation into the abdominal cavity with no hemorrhage whatsoever.

Again, one operates in tubal pregnancy because he is ignorant of the exact pathology in the *individual* case and, therefore, is in total darkness as to the prognosis.

That the influence of prognostic information is of great importance and that we should arrive at the most definite possible knowledge in order to do satisfactory work, is revealed in the changed attitude regarding the treatment of acute pelvic inflammation. Under Lawson Tait's teaching, an acute salpingitis meant that that tube must come out at once, and even my revered teacher, Joseph Price, held to this opinion to the last.

With a clearer conception of the pathology of acute pelvic inflammation, we know that acute gonorrheal salpingitis in the adult is without mortality, but the operation therefor is sometimes fatal. Operations, therefore, is delayed to the cold stage, when it not only is safer but more conservative as regards the other pelvic organs which are but temporarily involved.

Could we attain to the same degree of diagnostic differentiation in acute cholecystitis, acute appendicitis and tubal pregnancy, that we have in acute salpingitis, some of these cases would be left to the cold stage and operated upon with more safety and greater satisfaction.

In criticism of the foregoing, it can be said that it is elementary, which it certainly is, merely a primer of surgical philosophy. However, the reasons for presenting it seem to me sufficiently good to justify a few moments' time.

First. Just as the bulk of all obstetric work is done by the general practitioner instead of the obstetric specialist, so I am convinced the major part of all surgery is done by the general practitioner surgeon, and not the surgical specialist.

If this be true, the occasional surgeon must operate from the background of surgical authority as given in surgical literature, both textbook and periodical, and not upon the basis of his own knowledge acquired through research and extensive personal experience.

When surgical authority says operate at once for intestinal strangulation or perforation of the stomach or duodenum, the advice is absolutely sound because the patient otherwise is doomed, and even the most imperfect operative procedure may save life.

When the same authority says to do an immediate cholecystectomy for acute cholecystitis, an appendectomy for acute appendicitis or salpingectomy for tubal pregnancy, his advice is sound only if the disease is in its incipency or his advice is to the surgical specialists only, for *pari passu with the incidence of complications the operative prognosis increases in gravity*, whereas the disease prognosis remains exactly as it was at the outset. An urgent plea for early operation to be sure, but also a plea not to convert a possible natural recovery into an operative death.

Second. The technique of the average operating-room personnel and the technique of the occasional operator is likely to be founded upon a preponderance of experience with chronic disease. This includes profound anesthesia followed by field preparation, pedantic manual and instrument manipulation, meticulous asepsis and academic wound closure.

Unless the surgeon can change the pace of himself and his operating personnel, do his preparation before anesthesia, use local to shorten the time of general anesthesia if the latter is necessary, get into the abdomen, do only the absolutely necessary work, then get out with simple suturing methods, he has no right to operate upon these late cases. Acute cholecystitis *may* subside, large intraperitoneal abscesses due to appendicitis sometimes ruptures into the gut, the ovum dies or syncope stops the bleeding of many ectopics. Their prognosis untreated is not absolutely bad, but the prognosis of any of them after a formal deliberate operation, as for the disease in its early stages, is inexpressibly fatal.

The surgeon's satisfaction over a technically accurate and perfectly completed operative manipulation is not likely to be shared by the patient's friends or the public at large if the patient dies, and it behooves us always to look beyond the general diagnosis and its implication of an operation, to the question of prognosis, in which it has well been said that experience is fallacious and judgment difficult.

Third. The profession of medicine and surgery is under assault by all the under-educated vicious systems of cultism and quackery in existence, and it behooves all writers on surgical subjects to be discreet in their utterances, which go to the entire profession and often to the public, as well as the surgi-

cal specialist. It also behooves the individual who meets with a surgical condition to express himself clearly on the diagnosis and prognosis. After all, any profession will survive only as it meets with general public approval, and public opinion is based more largely upon the parallelism between the doctor's prognosis and the actual outcome than any other one factor.

As prognosis depends upon a minute differential diagnosis, anything which contributes to an accurate pathological diagnosis contributes, likewise, to an accurate prognosis, and here lies one of the drawbacks in the otherwise excellent movement known as hospital standardization. It is unfortunate that some term other than "standard" was not devised to meet this hospital reform movement, for *standardization* means standing still with our present knowledge, the limitation of which we all acknowledge.

It is unfortunate, too, that in accordance with the plan of this standardization, that man whose pre and post-operative diagnoses most frequently agree should be regarded as the most competent, because in the diagnosis of abdominal disease this tends to the use of those all inclusive terms "acute abdomen," a philological monstrosity, and "pelvic" or "abdominal tumor," so that the poor diagnostician can cover his lack of knowledge, while the man who says perforated duodenal ulcer and finds a perforated gall-bladder is presumed to have made a mistake. In this respect the present method of handling standardization puts a premium on the sloppy diagnostician which must be obviated sooner or later by insistence upon an accurate pathological diagnosis, but meantime prognosis suffers, and as prognosis suffers so does our standing in the commonwealth.

2007 Wilshire Boulevard.

FACTORS INFLUENCING THE MORBIDITY AND MORTALITY OF EXOPHTHALMIC GOITER

By JOHN HUNT SHEPHARD, M. D., *San Jose*

I wish to plead for a more careful classification of thyroid enlargements; to divide them into their pathological and also their clinical groups. To diagnose hyperthyroidism before exophthalmos and cardiac degeneration appear. For the present, to operate early. To carefully supervise the post-operative life of these patients, and, for the rank and file of us, to follow the paths proven to lead to the best results, leaving for those especially qualified and equipped the privilege and responsibility of experimenting with new methods.

I, unhesitatingly, state that I look forward to the time when thyroidectomy will not be the treatment for this disease as it is irrational to destroy a portion of any factory in order to curtail its output, but in the light of our present knowledge greater success is obtained by a properly performed thyroidectomy than by any other treatment.

DISCUSSED by C. A. Dukes, *Oakland*; J. H. Pettis, *Fresno*; C. G. Toland, *Los Angeles*; Vinton A. Muller, *Reno, Nevada*, and J. Wallace, *Salt Lake City, Utah*.

ALTHOUGH the literature is surcharged with reports on the morbidity and mortality of goiter, it is characterized by a paucity of definite information. The great majority of the reports are markedly lacking in a careful differentiation of the various types of thyroid enlargement, the duration of symptoms, and the degree of intoxication. In

studying these reports, one cannot help but feel that some have been diluted, so to speak, by combining the non-toxic group which have a very low mortality, with the toxic group which carry a high percentage of unfavorable results. In 1923, Pemberton published a most carefully classified report of 1296 patients operated upon for goiter in 1922. Of these 1296 patients, 633 had exophthalmic goiter. There was performed upon these 633 patients 1093 operations, with eleven deaths, a mortality rate per operation of 1.01 per cent, and per patient of 1.73 per cent. Six of the eleven deaths followed what might be called preliminary surgical treatment, i. e., ligation of the thyroid vessels and hot water and novocain injections. That it was considered necessary to perform 1093 operations on 633 patients, is evidence of the large number of highly toxic patients in this group. During the same period, 663 patients with non-toxic adenomata were operated upon with one death, a mortality rate of 0.15 per cent. If the two classes are combined, we find twelve deaths in 1296 patients, a mortality rate of .93 per cent, a figure which looks well in print, but which would be without meaning. This report of Pemberton's gives us a standard for comparison, and if his mortality rates are to be lowered it will be accomplished in the pre-operative and post-operative care and consideration given goiter patients.

It seems proper to ask why was it necessary to perform 1093 operations on 633 exophthalmic goiter patients? I believe the answer is, late diagnosis and later, submission to operation. In the early stage of Graves' disease the patient's ability to withstand surgical intervention is on a par with the patient having a non-toxic adenoma, and if we are to improve our results we must learn to recognize the disease before all the classical signs, as exophthalmos, tremor, tachycardia, and thyroid enlargement make their appearance. Exophthalmos rarely appears earlier than three months after definite disturbance of health, and in approximately 20 per cent of the patients never appears. Enlargement of the thyroid may be so slight as to easily escape detection, the characteristic tremor may be late in appearing or may be modified by some concomitant disease, and tachycardia may not be pronounced in patients with a B. M. R. as high as a plus 30. If we consider exophthalmic goiter as an acute intoxication, exerting its chief influence upon the energy production of the individual cells of the body, we will be able to make an earlier diagnosis, and the extreme picture of Graves' disease will become as rare as an appendiceal abscess. The first symptom of this intoxication is cerebral stimulation. The patient becomes more mentally alert; bodily movements quicken, and the daily capacity for work is often actually increased. This is soon followed by vaso-motor disturbance of the skin expressed by increased bodily warmth, perspiration and flushing, the result of an increasing radiation to compensate for the increased heat production. Tremor follows and the cerebral stimulation passes on to mental irritability. At this time the patient and her friends notice that she is nervous, and medical advice is usually sought. The blood pressures will show a little widening and, together with a slight or moderate acceleration of the pulse rate, indicates an in-

crease in the per minute output of the heart, made necessary to accommodate the increased cell metabolism which, in turn, is reflected in an increase in the B. M. R. Later, tachycardia, loss of strength and weight, in the face of a normal or increased food consumption, and cardiac insufficiency, as evidenced by exertion dyspnea follows in rapid succession, while bilateral exophthalmos adds its final touches to the picture.

The conception that exophthalmic goiter is an intoxication should be definitely impressed upon those responsible for the patient's welfare. The patient herself is irresponsible. She needs daily reassurance and positive firm opinions. Left to herself she wanders from one doctor to another, while the thyroid intoxication continues to increase and produce irreparable changes in vital organs. No matter what form of treatment is instituted, confinement to bed is essential, as by so doing the heart is relieved of that extra work required by activity over rest. The too prevalent custom of office-treating these patients cannot be too strongly condemned.

In the determination of their B. M. R., the load which these patients are carrying is weighed with the same degree of accuracy that we weigh a load of coal. But the size of the load is not the only factor to be considered. We must determine the ease with which the patient is carrying her load. An overload of 30 per cent may mean more to one patient than a 60 per cent does to another. It is essential to know the approximate date of the onset of symptom; whether or not there have been previous periods of marked hyperthyroidism, and of particular importance as to whether or not the intoxication is on the increase or receding. The cardiac reserve, which practically means the patient's ability to carry her load, plus the additional strain of any operative procedure, can best be judged by a study of the relationship existing between the pulse rate, the pulse pressure, and the B. M. R. A relatively low pulse rate with a relatively high pulse pressure and a given B. M. R. speaks for a better cardiac reserve than a relatively high pulse rate and relatively low pulse pressure with the same B. M. R. In the first instance the heart is accomplishing its task of furnishing an increased per-minute output by increasing the output of each beat, while in the second instance it is maintaining the increased per-minute output by increasing the number of beats per minute.

Next to the cardiac reserve the nervous stability of the individual is of prime importance. Apart from the restlessness, irritability and spasmodic crying, the variation in the pulse rate during the daily visitation deserves careful consideration. It is interesting and enlightening to use a pulse-computing watch, and note the variation in the pulse rate taken without, and then with the patient's knowledge that her pulse is being counted. Frequently, a variation of twenty to forty beats is noted, and whenever the variation under this test is over twenty beats, the patient is a poor risk for any extensive operative interference.

Since these patients are producing an excessive amount of heat they require an increased amount of water, and attention should be given the daily total output of urine and sufficient fluids adminis-

tered to maintain an approximately normal amount. To accomplish this may require the intake of three to four quarts of fluids daily. If the patient can or will not take that amount, then normal salt solution should be given per rectum.

Kendall and his co-workers were able to produce a modification of thyroxin, which contained but two iodine radicles; thyroxin proper contains three. The physiological effect of this compound was markedly different from the true thyroxin. This experimental work supported a belief which Plummer had held for some time, i. e.: That in exophthalmic goiter there is not only an increase in the quantity, but also a change in the quality of the thyroid hormone, and in March of 1922 he began administering iodine in the form of Lugol's solution to his exophthalmic goiter patients. No single discovery has been so valuable in the pre-operative treatment of this disease. Patients in an acute thyrotoxic crisis, unable to retain anything in their stomach will, after three to six doses of 40 min. of Lugol's solution per rectum, retain nourishment. Its effect upon the B. M. R. is marked. When given in 10 min. doses three times daily for ten days the B. M. R. will drop 15 to 40 points, and the patient's condition correspondingly improves. Under the routine use of this drug the necessity for preliminary ligations is reduced over half. Also under its use the vascularity of the gland is greatly diminished, its friability decreased, and a thyroidectomy made much easier.

The operative technique is so well standardized that the only question that arises is, will the patient stand a primary thyroidectomy, or shall some preliminary surgical procedure be employed? Upon the proper decision of this question rests the surgeon's mortality rate, and experience in evaluating the patient's cardiac and nervous reserve is essential for a correct answer. Doubt will often arise in the mind of the most experienced, and under such circumstance it is safest to employ the next less severe procedure. If doubtful as to the patient's ability to withstand the strain of a thyroidectomy, ligate a superior vessel; if only a mild or no reaction follows, then a thyroidectomy is safe a week later; if a severe reaction follows the ligation, then a week later do another ligation; and if a severe reaction follows the second, wait six to eight weeks before performing the thyroidectomy. Death following a thyroidectomy performed eight weeks following a double ligation is very rare.

The post-operative care and supervision of these patients is too frequently delegated to the other fellow. Immediately after returning the patient to bed from the operating-room she should be given a hypodermic injection of morphine, the dose depending upon the size of the patient, and as soon as she is quiet enough to permit proctolysis of 10 per cent glucose in a 5 per cent sodii bicarbonate solution should be started and continued until enough water is being taken per mouth to hold the urinary secretion up to normal. If for any reason proctolysis is not possible, then hypodermoclysis should be resorted to and never lose sight of the fact that these patients are burning at an abnormal rate, and water is as essential to them as it is to a racing automobile. During the first twenty-four to forty-

eight hours a small dose of morphine every six hours or oftener permits rest obtained in no other way. As soon as the stomach will tolerate the drug, Lugol's solution should be started and continued for three to four weeks. Metabolic studies show that within the first eighteen days the B. M. R. drops a little over one-half of what it was immediately before thyroidectomy. From this period the drop is slower and often the normal rate is not reached for three to six months. It must be remembered that the cells of these patients have been submitted to a heavy task, and six months should be allowed for their convalescence and no patient discharged as cured until their B. M. R. has returned to normal. The necessity for this prolonged post-operative rest and study is best explained to the patient and her family before any operative procedure is undertaken, otherwise they often feel that the surgeon has failed to accomplish what he expected and is trying to complete his work with medical treatment which might have been successful without surgery. We have even gone so far along this line as to refuse to operate until exacting a definite promise from the husband that he will provide competent help for his wife for at least six months. Some improve more rapidly if sent from home, while others are favorably influenced by home surroundings. Careful supervision of the post-operative life is essential if we are to secure the maximum results. Some have criticized us, arguing that since we ask so much medical support for our surgical work in obtaining a cure from exophthalmic goiter that surgery should not be a part of the treatment. I unhesitatingly state that I look forward to the time when thyroidectomy will not be the treatment for this disease, as it is irrational to destroy a portion of any factory in order to curtail its output, but in the light of our present knowledge greater success is obtained by a properly performed thyroidectomy than by any other treatment.

In conclusion, I wish to plead for a more careful classification of thyroid enlargements; to divide them into their pathological and also their clinical groups. To diagnose hyperthyroidism before exophthalmos and cardiac degeneration appear. For the present, to operate early. To carefully supervise the post-operative life of these patients, and for the rank and file of us to follow the paths proven to lead to the best results, leaving for those especially qualified and equipped the privilege and responsibility of experimenting with new methods.

Twohy Building.

DISCUSSION

C. A. DUKES, M. D. (Central Bank Building, Oakland)—To discuss a well prepared paper, to the facts of which we thoroughly agree, reminds me of the radio and its amplifications. Possibly, I can take some of the low tones of this paper and amplify them so that the emphasis would create a greater appreciation of the facts. The systematic manner in which Doctor Shepard has provided his argument of the factors involved, "The morbidity and mortality of exophthalmic goiter," impresses me as rational.

1. Education of the patient. It seems to me that too little attention is paid to the prevention of goiter. The young girl, and for that matter, the young man, should be taught to appreciate some of the consequences of the thyroid gland.

2. Shepard accentuates the importance of the relation-

ship between the physician and the surgeon. The pre-operative and post-operative treatment should be a close alliance of the physician and surgeon. Many, who have made an extensive study of the surgery of goiter, have called our attention to the necessity of a close study of the nervous economy and of the heart, and have pointed out to us how essential it is that the various steps should be carefully observed in the various types of goiter, particularly exophthalmic goiter, early and late. I have been particularly impressed with the details of Crile's method of safeguarding the heart and his particular care of the nervous economy. The infinite details which he gives to prevent shock are certainly all important influences in the morbidity and mortality of exophthalmic goiter. I particularly approve of post-operative supervision, the use of proctolysis, of glucose and soda and opiate; also, of the use of Lugol's solutions. Necessarily, the laboratory study, pre-operative, should be carefully observed.

Although I cannot be as hopeful of entire elimination of thyroidectomy as the author of this paper, I do believe that the long continued post-operative observation should be carried out by a physician who takes a particular interest in helping the surgeon cure this troublesome disease.

J. H. PETTIS, M. D. (Mattei Building, Fresno)—Doctor Shepard has so well summed up the toxic goiter question as we see it today and his views so nearly coincide with my own that I shall confine my brief discussion to on or two points which seem to me to be important.

Many of the mild hyperthyroid patients, with only a moderate increase in the metabolic rate, are found to have foci of infection, such as apical abscesses, infected tonsils. A considerable number of them are very definitely improved by the removal of these foci and I am convinced that not a few of them are permanently relieved of their symptoms by such treatment. Those patients who show only temporary improvement will come to operation in better condition for having had these foci eliminated.

In the severe thyrotoxic patient, partial removal of the gland is the only certain means of permanent improvement. I have seen a number of such who were markedly relieved by radium and x-ray. This improvement has been temporary. As a means of preparation for surgery, radium and x-ray treatment are comparable in value to polar ligation, but have the disadvantage that they increase the operative difficulties. Too, polar ligation, by the amount of reaction produced, gives us a fairly accurate index to the patient's ability to withstand lobectomy. By carefully following out the pre and post operative procedures so fully outlined by Shepard, many patients with beginning cardiac failure and even those with permanent irregularities can usually be carried through a skilfully performed lobectomy under local or gas oxygen anesthesia.

CLARENCE G. TOLAND, M. D. (523 West Sixth Street, Los Angeles)—Doctor Shepard's paper is one of great interest, both from the standpoint of the state in which we find our exophthalmic goiter patients and how we may reduce the mortality.

We believe that all cases of exophthalmic goiter are surgical at the present time, but they should be thoroughly studied before the time is set for the operation. Some of the patients may be ready in a very short time, while others will have to be under observation and carefully treated for many weeks before any type of operation may be safe.

We have had a great deal of satisfaction from the use of Lugol's solution as a preliminary treatment when associated with rest in bed, plenty of good food, and the elimination of coffee and tea. Lastly, these patients should be removed from the home surroundings and placed in the hospital where the operation is to be done.

Pemberton says, "There are three main factors that have helped to lower the operative mortality.

1. Pre-operative management; 2. Improvement in surgical technic; 3. The patients with exophthalmic goiter, coming to operation earlier, before visceral degeneration changes have taken place."

He further states, "Since the use of Lugol's solution as a preliminary treatment the number of primary ligations has been reduced 75 per cent."

There has been no great change in the operative tech-

nic. However, he believes that the surgeon has come to a better realization of the importance of nerve injuries, for instance, 95 per cent of the post-operative obstructive dyspneas are due to injuries of the recurrent laryngeal, while formerly we believed an injury to this nerve resulted in only cord paralysis.

He further states, "Since January, 1924, the operative mortality rate of exophthalmic goiter is 0.66 per cent. This is proof that iodine in the pre-operative treatment of exophthalmic goiter is of real value." Iodine treatment probably will not cure these cases without operation, however, we must remember there are a number of cases before the iodine period who recovered spontaneously.

We believe that some physiologic-chemist, who is associated with a physician, who understands exophthalmic goiter clinically, will give to the world some knowledge that will cure exophthalmic goiter without surgery. As we all know, there must be some sudden chemical change about which we know nothing, that we believe some day will be demonstrated to us.

VINTON A. MULLER, M. D. (Gray-Reid Building, Reno, Nevada)—Doctor Shephard covers the subject of Grave's disease in such an ideal manner in his paper and his views coincide to such an extent with my own, that in my discussion I shall simply attempt to elaborate on a few of the points brought out. In the beginning of his article, Shephard speaks of the need of careful differentiation of the various types of thyroid enlargement. Probably the most confusing type is adolescent goiter associated with tachycardia and increased nervousness with symmetrical swelling of the neck, especially if it is of the vasomotor type with thrills and bruits. The all-important factor of differentiation of this condition lies in the basal metabolic rate which is always increased in active Grave's disease, but is not increased and frequently may be below normal in the adolescent goiter herein mentioned. Adenoma, associated with hyperthyroidism, may be confusing at times, but should not be if one considers its nodular appearance, asymmetry, and the history of long-standing goiter with symptoms of hyperthyroidism appearing years after the first appearance of the goiter. These adenomas more definitely affect the cardio vascular system; they cause higher blood pressures, both systolic and diastolic, than are seen in Grave's disease. They leave one with definite hypertension. The basal metabolic rate is, as a rule, not as high in an adenoma associated with hyperthyroidism as it is in exophthalmic goiter.

I wish to emphasize how rapidly the beneficial influence of Lugol's solution passes upon withdrawal of the drug. When the maximum effect is obtained from its use, namely in about eight or ten days, and a ligation done at this time, abrupt withdrawal of the Lugol's solution after the ligation may precipitate a very severe reaction, whereupon the patient may not react to the second administration of the drug as quickly or as satisfactorily as she did primarily. Therefore, this drug should be continued after ligation or thyroidectomy, as before, and withdrawal effected gradually.

When ligating a superior vessel, it is not only important to identify the vessel, but one should include in the ligation a portion of the superior pole, as in this way, the sympathetic fibers entering the gland with the superior vessels are included. The reason for this is that the thyroid gland receives stimulation through these fibers.

In doing thyroidectomy it is important to thoroughly wash the field of operation with about 500 cc. of warm Ringer's solution before closing; this cleanses the wound of blood clots, debris, etc., and thereby relieves the patient of a certain amount of post-operative temperature and intoxication from absorption. These wounds do best if not drained. Four grammes of sodium bromide in starch water per rectum before awakening is of value in quieting the patient.

Lastly, I agree with Doctor Dukes that I can not be as hopeful as Doctor Shephard in the belief that thyroidectomy will eventually be entirely superseded by other treatment. Doctor Judd has quite recently reported 64 per cent of cures in 90 out of 100 operated cases of Grave's disease with 13 per cent markedly improved, and 5 per cent slightly improved after six years' time. Fifteen per cent of the series had died from various causes.

J. WALLACE, M. D. (Utah State Board of Health, Salt Lake City)—Doctor Shephard has succeeded in enumerating and emphasizing some very important factors in the morbidity and mortality of exophthalmic goiter, and in my opinion the views expressed by him are very much in accord with the now generally accepted thought regarding exophthalmic goiter. The value of educating the people, especially in goitrous areas, as to the means of preventing goiter and the necessity of seeking the best medical advice early, in the case of goiters that are becoming toxic, cannot be over-emphasized. An early diagnosis in these patients is just as important as the early diagnosis of a "lump" suspected of being cancerous. The early rest and freedom from worry Shephard insists on are also indispensable. The proper classification of the patient, not only as to her quantitative condition, but also as to qualitative, is highly important, for more and more, whatever may be the determining factor in producing exophthalmic goiter, we are coming to regard it as the outcome of what Worthin of Ann Arbor calls "an abnormal constitution." The patient must be studied not merely as one of a class, but as an individual. And it is Crile's pre-operative study of each patient, as well as his operative skill and technique, that has won him success in dealing with these toxic conditions. It is the duty of a surgeon to see that every other available helpful agency is used for these patients as well as the knife.

The unquestionable favorable results obtained in many places from the use of Lugol's solution as a part of the pre-operative treatment not only warrants its use for this purpose, but suggests that all goiters, whether simple or toxic, may start from a common cause, the one taking on the form of a deficiency, the other of a superfluity; a suggestion that receives further support from the fact that wherever in the country most simple goiter is found, there also we find most exophthalmic.

Many physicians will not agree that all patients showing signs of toxicity are subjects for operation, because some patients have recovered without operation. Over against this, there is to be balanced the injustice that may be done the patient by delay when ultimately operative interference may be necessary. If, however, patients could be seen by their physicians when the very first symptoms of toxicity that Shephard enumerated appear, his hopes for the abolition of thyroidectomy may be largely, if not wholly, fulfilled.

SOME PATHOLOGICAL CONDITIONS OF THE TONGUE *

By HOWARD MORROW, M. D., *San Francisco*, AND
LAURENCE TAUSSIG, M. D., *San Francisco*

Leukoplakia; cancer of the tongue; tuberculosis; syphilis.

DISCUSSION by Albert M. Meads, *Oakland*; Bertram Stone, *San Francisco*; Harry E. Alderson, *San Francisco*; Laurence Taussig.

ONE of the most common lesions of the tongue, and perhaps one of the least understood, is leukoplakia. This disease manifests itself clinically as a white patch of greater or less extent on the surface of the tongue or on the other mucous membranes of the mouth. It is accompanied by a thickening, varying from a scarcely perceptible elevation to a considerable warty excrescence. These lesions are of particular interest on account of the likelihood of malignant changes occurring if they are allowed to remain or are irritated by improper treatment.

Based on their clinical course, there are, in general, two types of leukoplakia. The one is relatively transitory and tends to clear rapidly without other treatment than a mild mouth wash plus the re-

*From the Department of Dermatology, University of California Medical School.

removal of the apparent cause. The other, similar in appearance and pathology, requires destructive therapy. Both types are usually the result of some sort of oft-repeated trauma, such as that produced by smoking or by the presence of a rough tooth, or they may be due to syphilis. It was formerly thought by most authorities that leukoplakia was practically always due to lues. This is generally conceded at the present time to be untrue. However, it is probably true that a syphilitic who smokes is more apt to develop these plaques than a non-syphilitic smoker, or than a syphilitic who does not smoke. Ragged teeth and ill-fitting plates occupy the same position as smoking as producers of chronic trauma of the buccal mucosa.

When a patient presents himself with leukoplakia, the first question asked is whether he smokes or not. It is well to note that if a person is susceptible to the formation of leukoplakia, a relatively mild tobacco habit may produce the needed trauma for the development of these plaques. If the patient smokes, he is urged to stop it entirely. The next point investigated is the condition of the teeth or plate. Here the services of a competent dentist are invaluable, though it is advisable to explain the type of examination and treatment desired. Finally, syphilis must be considered as an etiologic factor in every case. There is nothing about the appearance of the disease itself to suggest lues more in one case than in another, unless mucous patches, bald patches or scars are also present. A positive blood Wassermann reaction is helpful, but a negative report does not rule out lues. A history of a primary sore or of suspicious late symptoms may be obtained to help us. If there is any reason to suspect lues, anti-luetic medication should be given as a therapeutic test. In the very superficial leukoplakia a mouth wash of hyposulphite of soda solution may prove curative, particularly when combined with discontinuance of smoking or the removal of a bad tooth. In the moderately thickened type occurring in small localized areas, painting with supersaturated solutions of trichloroacetic acid at frequent intervals often clears the lesions. In the very thick or very extensive lesions, destructive measures alone are successful. Either radium, the actual cautery or some type of electrical destruction must be used. Of these, radium has proven most successful in our hands. Following any of these forms of treatment, however, the lesions may recur and may require repeated treatment.

The pathology of leukoplakia is similar to that of seborrheic or senile keratosis, namely, a hyperkeratosis with acanthosis, a thickening of the rete pegs, and a round cell infiltration. A certain amount of fibrosis may be present.

Carcinoma of the tongue is one of the more common forms of malignancy, and it is of interest on account of the varieties that occur and because of the frequent difficulty in making a diagnosis. Many still believe that the removal of a piece of any growth for microscopical examination is dangerous. We have agreed for some time, with the growing minority, that in these cases a biopsy never causes trouble, providing it is taken from the central portion of the growth, rather than from the border, and providing the least possible trauma is produced.

Nevertheless, we have hesitated to remove a specimen except when there was a doubt as to the diagnosis. Carcinoma of the tongue often arises on an old leukoplakia, on a luetic glossitis, or on a gumma of long standing. A pre-cancerous lesion does not always occur, however. In general, there are two clinical types of tongue cancer. The one is indurated and infiltrating, usually grows rapidly, metastasizes early and is resistant to therapy, though occasionally cured by radical surgery or by efficient radium treatment. The other is papillomatous, slow-growing, late in metastasizing, and is frequently curable by surgery, radium, or the actual cautery. The latter type, unfortunately, is far less frequent than the first. Pathologically, the indurating type is almost invariably a squamous-celled epithelioma, presenting the typical prickle cells invading the structure of the mucous membrane; usually, however, showing less pearl formation than is ordinarily seen in squamous-celled carcinoma of the glabrous skin or of the lip. The papillomatous carcinoma of the tongue is microscopically similar to a benign papilloma at the outer portions, the cells being arranged in regular finger-like formation, with few or no mitoses and little variation in the size and shape of the nuclei. Sooner or later, however, these papillomatous tumors invade the submucous tissue of the tongue, and the growth loses its relatively benign character. Clinically, the papillomatous carcinoma is readily recognized. It may infrequently be associated with leukoplakia. In recognizing the indurating type, it is necessary to differentiate it from a gumma and from a tuberculous ulcer. An ulcerating gumma of the tongue of long standing occasionally shows malignant changes, and this increases the difficulty of making a differential diagnosis. It sometimes happens that a patient presents an apparently typical long-standing syphilis of the tongue. His blood Wassermann is positive, and anti-luetic therapy causes marked improvement at once. However, further treatment results in less benefit, and we find that a carcinoma remains. Probably the most satisfactory procedure would be to take a specimen of the growth in every case, as well as a Wassermann or therapeutic test. It is well to remember that a negative pathological examination is not necessarily conclusive. It happens now and then that the biopsy is taken from a non-malignant area. This is likely to happen once in a while in taking relatively small biopsies from almost any tumor, and the likelihood is increased when we are dealing with a non-malignant granuloma that is just beginning to show malignant degeneration. When this happens, only the subsequent course puts us on the right track.

Tuberculosis of the tongue is a rare condition. This is particularly true of primary tuberculosis of the tongue. Tuberculosis of the tongue in patients with advanced generalized tuberculosis is usually readily recognized, as the physical examination gives a clue to the mouth condition. A tuberculous ulcer of the tongue in a patient who presents no other manifestations of tuberculosis must be differentiated from a primary syphilitic sore, an ulcerating gumma, a traumatic ulcer, and an epithelioma. A tuberculous ulcer is apt to be painful, comparatively superficial, irregular, undermined, and the neighboring

glands may be enlarged. All of these symptoms may be found in a primary lesion of syphilis, and the only positive method of making a diagnosis in such a case is by finding the spirochetes in a dark field preparation. These are the cases in which a biopsy is usually unsatisfactory, as the pathologist can seldom differentiate a tuberculous ulcer from a syphilitic ulcer. In sections, both show a predominating round-cell infiltration, with many endothelial cells. In a luetic lesion this infiltration is usually most marked about the blood vessels, but this is not always sufficiently marked to be a differentiating factor. In either case there may be numerous giant cells and in both cases they may be of similar type, with the nuclei arranged peripherally in a more or less definite horseshoe formation. These particular giant cells are more common to tuberculous lesions than to syphilis. In both lesions there is often more or less destruction, but we only see typical tubercles with caseation in advanced cases of tongue tuberculosis. The luetic lesion is apt to be more vascular than the tuberculous lesion. The rarer types of tuberculosis of the tongue are the deep nodular type and the papillary type. Biopsies in these types are contra-indicated, as the resulting ulcers are apt to be chronic and painful. Consequently, in differentiating syphilis and carcinoma from this type, it is preferable to use a therapeutic test.

A therapeutic test should never be given a patient with a suspected chancre of the tongue until repeated dark fields have been resorted to. An ulcerating gumma of the tongue is usually recognized, as the ulcer is deep, the neighboring glands not enlarged, the dark field examination is negative, and the ulcer will clear promptly under the usual anti-luetic therapy.

Fitzhugh Building.

DISCUSSION

ALBERT M. MEADS, M. D. (1706 Broadway, Oakland)—Such a paper as presented here by Dr. Morrow and Dr. Taussig calls our attention again to lesions of the tongue, and proves the value of reiteration. Tongue lesions are often overlooked or belittled until they have reached a stage beyond repair.

Many cases of leukoplakia, before the days of radium, passed from one office to another, with very little permanent improvement, finally degenerating into malignant growths. In these pre-cancerous lesions, gratifying results are now being obtained with radio-therapy. Tongue lesions of the malignant type once called for mutilating operations, with poor results. All of us now welcome the use of radium in these cases, as the results are at least as good, if not better, under such treatment. The limitations of the Wassermann test have been emphasized, and should be taken to heart. Often a therapeutic test clears up the lesion as well as the diagnosis.

Such a paper as this, drawn from a large clinical experience, should be, from time to time, accessible to the general medical reader, as well as to those interested in dermatology, in order that the patient may receive the benefit of an early diagnosis. I am glad of the opportunity of commenting on, if not adding to, this instructive article.

BERTRAM STONE, M. D. (Flood Building, San Francisco)—This article seems to cover the subject in a very comprehensible manner.

As noted and, I think worth repetition, leukoplakia of the tongue and other mucous membranes of the mouth are, from the standpoint of treatment, either very easily gotten rid of or only with great difficulty and by radical treatment used in a thorough manner—radium or the actual cautery. As one cannot always determine the actual difficulty confronting one, it is wise not to give too

positive and clear-cut a prognosis. In my practice, I have seen more cases in women and non-smokers than in men; which, however, only indicates the danger so frequently indulged in, of arriving at conclusions on small numbers of cases. Bad teeth and poorly finished plates have been the most frequent exciting causes, and proper dental treatment and oral hygiene have been all the therapy needed; this, of course, only refers to the more innocent type of cases.

The old idea of a syphilitic etiology in all cases, at one time held by all, and at present by many, is exploded. Many, with what seems good logic, claim that it has no relation whatsoever to leukoplakia, but the majority of evidence still seems to accord it a place in the etiology. Tobacco seems to have a real connection in its production. However, as leukoplakia is practically confined to the ages of 20 to 60, and is most frequently seen in men who usually smoke, but who seldom quit just because they are 60, one might wonder if, after all, it might not be a coincidence only.

Carcinoma of the tongue is such a distressing and serious condition and the surgical treatment so radical, disfiguring and disappointing in results, if radium can offer even as good results as surgery it should be the method of choice. A point well worth reiterating is that gumma and carcinoma are often combined, and one should not continue anti-luetic treatment for any great length of time unless the lesion rapidly disappears as a whole.

Tubercular ulcers of the tongue and lips may occur in patients in whom no evidence of tuberculosis can be found elsewhere, a point well worth stressing, being a fact not generally recognized. Pathological examination, possibly a therapeutic test and a remembrance of the above mentioned fact will usually make its nature evident in a short time, if not at once.

HARRY E. ALDERSON, M. D. (240 Stockton street, San Francisco)—The writers are to be commended for placing this important subject before the profession again, because early prompt treatment of these conditions is of such vital importance. Too often we see these lesions presenting advanced degenerative changes which might have been prevented had they been taken care of early. The fault usually lies with the patient, for he is inclined to temporize even when advised regarding his trouble, until pain or other symptoms finally make him submit to treatment.

The etiology of leukoplakia and carcinoma of the tongue have been covered by the writers. It is remarkable how many of our cases of malignancy of the tongue and buccal mucosa at Stanford are seen in patients with syphilis. We have seen carcinoma cases where arsphenamin treatment of the lues has been followed by acceleration of the growth of the carcinoma—possibly due to the stimulating effect of repeated doses of the arsenic. Also the administration of mercury is very apt to increase irritation in the mouth, which, of course, is bad for the carcinoma. Certainly, the sooner malignancy is recognized and radium and roentgen therapy or surgery (or all combined) are initiated, the better it is for the patient. I believe that it is a mistake to carry out long preliminary courses of anti-luetic treatment where malignancy is progressing rapidly.

The making of dark field examinations of material from the mouth has been mentioned. It must be said that the difficulties here are great. One cannot always differentiate between the treponema pallidum and the spirocheta dentium. Noguchi has said that he finds it impossible at times. Buccal lesions of all kinds teem with enormous numbers of spirochaetae of various types, and the sp. dentium is almost certain to be present. Fortunately, however, there are other diagnostic aids that may be utilized.

I have seen beautiful results from Taussig's treatment of carcinoma with radium. Had I early carcinoma of the tongue, I most certainly should have him implant the radium emanation tubes in the same, for in my opinion that is the best treatment to date.

LAURENCE TAUSSIG, M. D. (closing)—I should like to insist upon the fact that a therapeutic test in doubtful mouth cases does not mean the giving of a complete course of anti-luetic therapy. If the response to one or two injections of full doses of arsphenamin or neoarsphenamin does not amount to 50 per cent improve-

ment or more in two or three weeks, the test should be considered negative and further diagnostic aids should be used, especially a biopsy. Though agreeing with Doctor Alderson that a dark field examination of a tongue primary is not simple, we believe that one experienced in recognizing treponema pallidum would have little difficulty when the material is obtained from the depths of the lesion rather than from the surface.

HEAD PAINS OF OCULAR ORIGIN

By RODERIC O'CONNOR, M. D., San Francisco

This is the type of paper, and it is followed by the type of discussion that particularly pleases a medical editor. It contains messages of interest and importance to every physician, be he general practitioner or specialist.—EDITOR.

The percentage of all headaches due to ocular disturbances is difficult to determine. Estimates vary from 50 to 90 per cent, but probably 70 would be a fair one.

Many patients show, by ordinary tests, nothing wrong, and yet there is definite eye disability.

The frequency with which eyes are blinded by a failure to recognize this disease is a sufficient reason, in itself, to serve as a cause for prohibiting the examination of eyes by non-medical individuals.

Pains in the base of the skull and upper cervical region are frequently of ocular origin, the causes being those conditions that call for a change in the position of the head to compensate, such as oblique astigmatism, vertical deviations, cyclophoria, and the various forms of paralyses of the ocular muscles.

Proper use of well-proven methods should enable any ophthalmologist to determine whether or not the muscle imbalance is the cause of the symptoms.

The ophthalmologist who fails to prepare himself to handle properly this type of work or who goes a step farther and warns his patients against those who are prepared to do so is, in my opinion, not practicing his specialty fairly either to himself, his patients, or to those ophthalmologists who are seriously trying to help such patients.

DISCUSSION by Raymond J. Nutting, Oakland; J. O. Chiapella, Chico; George W. Jean, Santa Barbara; Hans Barkan, San Francisco.

IT IS the common belief among the general public, and not very uncommon even among medical men, that, if headaches or other symptoms of eyestrain are not relieved by glasses, nothing further can be done. It is only in this way that we can excuse the frequency with which medical men refer patients to opticians for ocular examination. In doing so they apparently forget that the examination of the ocular apparatus is as much a medical affair as one of the heart or lungs. To illustrate this point I might cite two cases occurring recently, both of whom had been under the care of opticians. One was a case of chronic glaucoma that had progressed so far that in one eye direct vision had been involved, and in the other the visual field had been reduced to within ten degrees of the fixation point. Both eyes required operation. The other case was one of tobacco amblyopia with a central scotoma so advanced that light perception was absent in that area. Like other such cases, the worse the vision became the more he smoked to pass away the time.

The percentage of all headaches due to ocular disturbances is difficult to determine. Estimates

vary from 50 to 90 per cent, but probably 70 would be a fair one. It is evident that the frequency with which the eyes are proven to be the cause will depend on the completeness of the ocular examination, the correct interpretation of findings, and the proper carrying out of the right treatment.

Many patients show, by ordinary tests, nothing wrong, and yet there is definite eye disability. Most of these, on more detailed study, turn out to be examples of hidden troubles of the extra-ocular muscles; some are instances of mild or beginning glaucoma; others have the source of a reflex eye disturbance in the intranasal or dental regions.

One of the patients cited above shows the importance of always having in mind the possibility of glaucoma. I am now studying another patient with marked asthenopia, in whom an accurate refraction and all possible muscle tests have given negative results. An atypical cupping of the disk led me to think of glaucoma. Pilocarpin was prescribed, and a definite improvement in symptoms resulted. After a week of such treatment, the ocular tension was found to be 30 mm. of Hg. in the right eye, and 18 in the left, the latter figure being normal. His vision and visual fields are normal, so if further study should prove the trouble to be glaucoma, the diagnosis will have been made at the right time.

The frequency with which eyes are blinded by a failure to recognize this disease is a sufficient reason, in itself, to serve as a cause for prohibiting the examination of eyes by non-medical individuals.

Many eye headaches are typically migraine, as far as the symptoms are concerned. The fact that it may be hereditary has no diagnostic significance as ocular defects are even oftener so. Neither does vomiting indicate true migraine, as nausea, with vomiting at times, is a rather common symptom of certain forms of eye troubles. I have frequently seen the scintillating scotoma of migraine (supposedly) disappear after relief of eyestrain.

Most patients are able to definitely relate their headaches to overwork of the eyes. Others cannot but state that the headache is present all day except on waking. Early morning headaches are more often nasal in origin. Women complain of shopping headaches. Many have them after riding on cars or autos or under other conditions where the eyes have to make frequent changes in position to follow moving objects. These are usually found to have disturbances in the extra-ocular muscles, the compensation for which is especially difficult when the eyes must follow moving objects. Rarely a patient will state that there is less discomfort in the near than the distant use of the eyes. One such patient of mine had a divergence of such a degree that, for distance, he could not avoid the desire for binocular vision, while for near the strain was so great that he simply allowed one eye to diverge. Such a case shows the importance of figuring out an apparently inconsistent symptom.

While the consideration of intracranial pressure is out of place, please remember that its diagnosis is often first made by the ophthalmologist while investigating headache. To show again the harm done by opticians, I wish to cite a case of brain tumor seen by me for Dr. Albert Rowe, in which headache and failing vision had been treated by an opti-

cian for several years. She had paid for many pairs of lenses. When she finally came under competent medical care the condition was so advanced that operation was done only as a forlorn hope.

Pains in the base of the skull and upper cervical region are frequently of ocular origin, the causes being those conditions that call for a change in the position of the head to compensate such as oblique astigmatism, vertical deviations, cyclophoria, and the various forms of paralyses of the ocular muscles.

We must, therefore, conclude:

1. That the ocular apparatus must be thoroughly studied in all cases of headache where the cause is not very evident.

2. That no physician should allow his treatment of a patient with headache to be influenced by the results of an ordinary refraction.

Headache, as you all know, is a pain felt in the dural terminals of the trigeminus, the dural branches of the upper cervicals, and the recurrent dural branch of the vagus. Of these, the trigeminus is by far the most important. Anatomy teaches that the centers of the third, fourth, fifth, sixth, and seventh cranial nerves form a closely related group, all interconnected, and that the fifth is the sensory nerve for the area supplied by the others as motor nerves. Therefore, it is in the reflex arc of these four nerves, three of which are motor nerves for the ocular muscles. Moreover, there are communicating branches from its ophthalmic division to the oculo-motor nerves, these being the nerves of ordinary sensation to the ocular muscles. Therefore, we have three possible explanations for reflex ocular headaches:

1. Pure overwork of the oculo-motor centers, with overflow of the irritation to the nearby fifth center.

2. Direct irritation of the sensory terminals in the overworked muscle, which irritation is referred back to the fifth center.

3. Direct irritation of these sensory terminals by fatigue toxins generated in the overacting muscles.

However the fifth nerve center is irritated, this is projected out to its dural terminals to be interpreted as a headache.

In connection with the ocular conditions to be described, it is important to remember the following well-established points in muscle-nerve physiology.

1. All muscle tissue has a tremendous reserve power which cannot be elicited by *normal action* of the nerve cells, therefore it can never become exhausted as a result of such action. This is shown by the fact that muscles can be electrically stimulated to powerful contractions after the power of voluntary contraction is lost by exercise.

2. Nerve cells tire comparatively rapidly on continued action, but recuperate rapidly as compared with muscle tissue which, once thoroughly exhausted, takes a long time to rebuild itself. In this way the muscles are protected and are always in condition to respond to *normal impulses*.

3. Intermittent action of muscles, allowing proper intervals for rest, results in growth with a corresponding increase in endurance.

4. *Continuous or too frequent contraction causes rapid fatigue.*

Aside from glaucoma, which has already been mentioned, and certain acute inflammatory conditions of the eyes, I wish to consider the following ocular causes of headaches:

A. PUPILLARY ASTHENOPIA—This is due to overstimulation of the pupillo-constrictor mechanism by excessive glare. It is rather common in the tropics and desert regions. At times it results from excessive artificial illumination when there is exposure to the direct glare of high-power electric lights. Photophobia occurring under ordinary conditions often disappears when errors in refraction or muscle balances are corrected. Therefore, tinted lenses are not in order, simply because the patient may complain of a sensitiveness to light. The real cause should be searched for. Normally, the pupils contract with accommodation and convergence. An undue contraction of the pupil, made necessary by glare, may throw this associated action out of balance.

B. REFRACTIVE ERRORS—1. *Hyperopia*. In this condition the accommodation is in action even for distance; therefore, the ciliary muscle is at work whenever the eye is open. The normal relation between the accommodation and convergence is altered by the necessary increase of the accommodative effort over the convergent. So when corrective lenses are given to relieve the ciliary muscle, this acquired habit must be broken. As long as it persists the patient will complain of his glasses.

2. *Myopia*. Myopic eyes are lazy, the accommodation never being necessary except within the focal point. If this happens to be that of the reading distance (thirteen inches) the only exertion will be one of convergence. When the correction is given to permit clear distant vision, the eyes are forced to work as much as the normal. For this reason myopes often complain bitterly that they feel much worse with the glasses, in spite of the good vision.

3. *Astigmatism*. The oblique forms are especially important as objects are twisted. This twist is compensated by action of the oblique muscles to rotate the eye about its antero-posterior axis or by head tilting, or by both. Glasses render this unnecessary, but the habit persists and causes trouble till the eyes learn to let the lenses do the work. In certain cases of very high astigmatism the mechanical disadvantage in the lens correction are so great that they cannot be worn. In some of these, operative measures are worth while. I have recently had such a case where an astigmatism of nine diopters was reduced to four by a thorough cauterization of the cornea at right angles to the direction of the defect. The vision, as corrected, improved from 20/100 to 20/30.

4. *Anisometropia*. In this, the eyes differ so much in their refraction that satisfactory binocular action with the corrective lenses is often impossible. Occasionally, as mentioned under the preceding heading, the difference may be reduced to bearable limits. Rarely we see what appears to be an impossible situation. I have had such a one with one eye emmetropic, the other highly myopic. For some rea-

son she had severe headaches. I extracted the lens from the myopic eye by the needling method, reducing its error from minus 24 to minus 4 diopters, and improving the corrected vision from 20/70 to 20/30. The headache disappeared.

5. *Presbyopia*. In early presbyopia the symptoms are often disproportionately severe, due to the overaction of the ciliary muscle necessary to obtain the proper change of focus in the hardening lens. In this connection it must be remembered that we can use continuously only two-thirds of our total power of accommodation. Lenses usually give relief, but even here we are dogged by trouble in the form of bifocal glasses and the difficulty patients have in adjusting themselves thereto.

C. DISTURBANCES OF THE EXTRA-OCULAR MUSCLES.

Leaving out of consideration cases of actual strabismus and of paralysis, we have the following:

1. *Esophoria*, where the visual axes tend to converge and the corrective effort falls on the divergers. When of any amount, the strain is severe, as normally there is no great call for the divergers to work. In one case the symptoms were so severe from six degrees, that the boy had to give up his course in law. Non-operative treatment failed to secure the desired result, which was obtained by shortening of one externus.

2. *Exophoria*, where the visual axes tend to diverge, calling for correction by the convergers. A greater degree of exophoria can be borne, because the convergers can stand the strain of correction better.

3. *Cyclophoria*, when the vertical axis of the eye tilts in or out. The correction must be made by the oblique muscles.

4. *Hyperphoria*, when one visual axis is higher than the other. This condition causes symptoms out of all proportion to the amount as, in its correction, an entirely abnormal action of the muscles must be made. Normally, both eyes either look up or down, but here one must turn up while the other turns down, to bring both to the proper level. Dr. Stevens, who was one of our greatest authorities on the ocular muscles, estimated that one degree of vertical deviation caused symptoms as severe as fifteen of horizontal. I have seen cases of marked disability from one degree. Luckily, prism corrections are borne better in hyperphoria of low degree. Vertical deviations frequently cause head tilt in order to bring the eyes to a level and so save the ocular muscles. This tilt carries the corresponding shoulder down, which, in turn, might cause a curvature of the spine. All this in a purely mechanical way. Another common sign is an elevation of one eyebrow through the associated action of the frontalis, in the effort to hold the lower eye up.

In all the above-mentioned conditions, the corrective strain is present as long as the eyes are open, even though not in use for near, and therefore is an example of continuous exhausting work.

5. Insufficiency of convergence when the visual axes cannot be converged close enough to permit continued use of the eyes at the ordinary reading distance. It has been proven that one must be able

to converge the eyes easily to four inches from their centers in order to perform prolonged work at thirteen inches. In other words, at least two-thirds of the total power must be in reserve. In this connection the patient's occupation must be considered, for, even though he may give a normal test, he may have trouble if his work is done closer than thirteen inches. One case of mine that illustrates this was an old copper-plate engraver, who worked at a distance of about seven inches. He had been unable to work for several years, in spite of normal vision and an entire absence of trouble in reading. Previous examiners had overlooked the question of convergence strain, and all he needed was a pair of prism binocular magnifiers to enable him to get back to work. Frequently, in these cases the balance of the eyes for distance is normal, so all the symptoms are related to the near use of the eyes.

TREATMENT

1. *Glaucoma*—This is too large a subject. The important point is diagnosis. Miotics are then in order. If the tension and symptoms are controlled, well and good, but if not, operation must be performed.

2. Refractive errors call for lenses.

3. Imbalances of the extra-ocular muscles call for:

(a) Non-operative measures, such as lens correction, with exercises and possibly prisms in suitable cases.

(b) Operative measures. Until one is converted to the belief that true imbalances are anatomic in origin, he will not have the faith to learn the right surgical methods available for their relief and the methods of diagnosis needed to determine the place at which to apply the surgical work. We all know the bad effects, mechanically and symptomatically, that follow an operation incorrectly done or placed. Why not acknowledge the probability of developmental and acquired anomalies similar in effect? When one does not believe that the basis of true muscular imbalance is an anatomic defect in power or attachment to the globe, he is likely to feel that operative work on the muscles is working at the wrong place and so fall into the common practice of "do nothing," which means, very often, prolonged and unnecessary suffering for the victim.

In this connection I wish to emphasize that the object of an operation is primarily to relieve symptoms. *Proper use of well-proven methods should enable any ophthalmologist to determine whether or not the muscle imbalance is the cause of the symptoms.* If the discomfort and disability, so proven to be due to the muscle imbalance, cannot be relieved by non-operative measures, what else is left? It is ridiculous to lay down on the job and wait for a miracle. *The ophthalmologist who fails to prepare himself to handle properly this type of work or who goes a step farther and warns his patients against those who are prepared to do so is, in my opinion, not practicing his specialty fairly either to himself, his patients, or to those ophthalmologists who are seriously trying to help such patients.*

There are two general types of operations: (a) Tenotomies; (b) shortenings.

(a) Tenotomies must necessarily be done on the muscle not primarily at fault. To illustrate: Suppose a case of vertical deviation with the left eye higher because the right superior rectus is paretic. Should we tenotomize the left superior rectus, and so have two paretic muscles, or should we shorten the right superior rectus and so approach equality in strength? An answer is hardly necessary, provided the operator knows how to shorten a muscle in a safe way.

(b) Shortenings can be done in many ways, but of them all the "tuck" and an operation devised by myself are the *safest, in that no harm can result*. In the tuck, sutures are used to hold the shortening, while in my operation none are necessary, strips of the tendon being looped about strands of shortening material laid transversely to the tendon. I got the idea from the method of shortening saddle girths used by cavalrymen in our military service, and have used girths so shortened for years. A model is being passed around with the central third shortened in this way to show, by the slack in the lateral portions, the actual amount of shortening. Any force short of actual breaking of the strands can be withstood. In the ocular tendons this relieves the operator of any fear of loss in effect through slipping of stitches along the parallel fibers of the tendon. This method is so safe that I can, without fear of causing harm, operate on deviations of low degree and on little children for strabismus as early as the fourth year.

There is an ocular condition causing headaches that seems to be immune to treatment, that is direct treatment, called retinal asthenopia. This is similar to neurasthenia in general. However, I find that the more I go into my cases, hunting for hidden muscular defects, the less frequent becomes my diagnosis of this trouble.

The frequency of the above described conditions is great, and the troubles they cause are apparently disproportionate until one remembers the mechanisms involved. In children they often cause marked "nervousness" and backwardness in studies.

Finally, I wish to repeat for emphasis: The automatic correction of these imbalances means a continuous action during the waking hours of the nerve centers and muscles involved. This, as shown by the established facts of muscle-nerve physiology, is productive of the direct and remote symptoms of fatigue.

909 Hyde Street.

DISCUSSION

RAYMOND J. NUTTING, M. D. (Medical Building, Oakland) — Doctor O'Connor has thoroughly gone into the cause from every angle, and it is as it should be, because too many medical men today are not thoroughly examining their patients, and we all know the result. I certainly agree with him in regard to too many medical men referring their patients to opticians every time they complain of poor vision. I have had two patients in the last month who are nearly blind as the result of glaucoma. The first was getting electric treatments and muscle exercises by an optometrist, with the vision getting worse all the time, while the second was getting her glasses changed about every month, and as a result losing both vision and money.

We know that ocular disturbances cause a good many headaches, but should remember that refractive errors, by themselves, do not by any means cause all the trouble, as so many men would have us believe. For the refractive errors, astigmatism is the most common cause, with hyperopia next, and myopia by itself very seldom.

We should never overlook the fact that we should take a careful history of every patient examined and rule out any other cause of the headache for which the patient seeks relief. Also at the same time we should always remember that any direct or indirect irritation of the fifth nerve is the seat of the trouble. Next, as mentioned before, a very thorough medical eye examination should be made. By that I do not mean simply taking the patient's vision and fitting him with lenses, but, in addition, a very careful study of the extra-ocular muscles, the visual fields and, of course, the external and internal examination of the eye itself with the proper instruments; at the same time thinking of the eye as an essential part of the body, and not as a little kingdom all by itself.

One will be surprised in the large number of patients who are having trouble as the result of muscle imbalance, and of this group the vertical deviations give us a greater amount of symptoms. As to the method of correcting these muscular anomalies, I thoroughly agree with O'Connor that the weak muscle should be made stronger by a shortening operation. Cutting a strong muscle always looks to me as if we are not giving our patient a fair deal, as we too often feel it is the easiest way out of the difficulty for the doctor himself but not for the patient, as too often happens. I have had the opportunity of seeing O'Connor operate on several muscle cases, and it is a pleasure to see him work. The operation which he has worked out for shortening a muscle is very clever and, furthermore, you get results when it is done properly on the correct muscle. This is the reason, to my mind, why O'Connor gets results and other men do not when attempting the same operation. In closing let me again emphasize: Study your patient carefully, always keeping in mind the oath of Hippocrates, which a good many of us forget at times.

J. O. CHIAPELLA, M. D. (Chiapella Building, Chico, California) — It is my firm belief that 80 to 90 per cent of head pains are of ocular origin, and that the ophthalmologist who thoroughly examines his patient for refractive errors will arrive at a similar conclusion. It all depends upon how thorough your examinations are—how much patience you possess to see that your examination is thorough.

Doctor O'Connor's statement relative to medical men referring patients to opticians strikes a popular chord, and I regret to say that the medical man who does it oftentimes is the type who treats a case of glaucoma as an iritis and prescribes atropine, with disastrous results, or thinks a chronic case of trachoma is a conjunctivitis and recommends argyrol with consequent argyrosis, not realizing that argyrol is a silver salt.

Head pains due to nasal disturbances are usually so localized as to site as to suggest the possible origin; or the history, especially of morning or lower half headache, completes the picture, and you can go astray *very* seldom.

I'm very much interested in his operative work on the extra-ocular muscles, knowing from experience that they frequently are the source of disturbance and are often overlooked in examinations, either from thoughtlessness or through not giving them their proper value. Hyperphoria, I find, respond most readily to prism correction, giving complete comfort, as a rule, and usually a grateful patient.

Pupillary asthenopia is of frequent occurrence in the Sacramento Valley and is due to the excessive glare of our summer sun, and while I recommend Crookes lens oftentimes to my patient, I do it more because it is expected of me rather than any particular belief in the virtue ascribed to them; the correction of the proper refractive error or muscular imbalance will do more to clear up the condition than the wearing of Crookes lens.

Finally, it will be a genuine pleasure to me to see O'Connor's work on some of the muscular anomalies he has mentioned; it is a field that is wide, and the way to it has been closed to the many men who are practicing ophthalmology and I find myself one of that greater number, but I expect to avail myself of the opportunity of overcoming my lack of knowledge and skill in that direction.

I cannot too highly compliment Doctor O'Connor on the thoroughness with which he has covered his subject, for his paper is one of genuine practical interest to any ophthalmologist who really has the interest of his patient at heart. His conclusions can hardly be questioned.

GEORGE W. JEAN, M. D. (Santa Barbara, California) —

Doctor O'Connor's paper is timely, in that it calls attention to the necessity of an early diagnosis in glaucoma and warns physicians of the fallacy of believing lenses a cure-all and an end-all for headaches of ocular origin. It is hard to believe that any ophthalmologist today, in searching for the cause of his patient's headaches, stops with the mere examination for lenses, yet it is true that ophthalmology suffers from the widespread idea that headaches are mostly refractive, from which arises the confusion of an ophthalmologist with a refracting optician (or his glorified successor, the optometrist) in the minds of the people and unfortunately, at times, in the minds of physicians. Yet it is also true that many an eye has been rescued from hopeless blindness because the average individual has a fixed belief that if he suffers from headaches his eyes should be examined. That he does not always make a wise choice, is unfortunately true. Every ophthalmologist has seen cases of glaucoma treated all too long by someone for neuralgia, migraine, or what-not. Headaches due to muscle or refractive errors are deplorable enough if not relieved, but the most tragic cases of all are the glaucomas. O'Connor's experience has been fortunate in relieving that frequent form of headache associated with zigzag flashes of light—the so-called scintillating scotoma. I have never helped a single case either by any glasses or any treatment, and my consultants have likewise failed.

HANS BARKAN, M. D. (516 Sutter Street, San Francisco)
—Doctor O'Connor's paper puts the issue squarely up to the medical man. There is no excuse for his ever sending a patient with headaches to an optician. I have, as have all other ophthalmologists, seen enough people who were beyond medical aid due to the fact that they received unnecessary expensive glasses from an optician when the diagnosis of impending blindness, due to glaucoma or other causes, would have been made by an ophthalmologist at a time when there was still some hope.

I have not been as fortunate in curing true migraine by glasses. I do not believe that the real "familial" headache, accompanied by nausea and scintillating scotomata, can be cured by glasses. If these patients have errors of refraction they can be made more comfortable, but in my experience the attacks continue, although in some cases somewhat less pronounced.

I admire the clear and concise, yet comprehensive, fashion in which O'Connor has presented the very complex subject of muscular imbalance and its treatment. I agree with him on the main essentials. He has, however, not discussed the importance of that class of patient who improves so markedly in symptoms or loses them entirely if relieved of nervous strain and overwork—of that class in which the symptoms occur after some debilitating sickness, loss of weight, etc., and disappear when the patients are again in good health. In these people the muscular imbalance is there, whether they have symptoms or not. They have no symptoms if they feel well. That has always led me to doubt that all imbalance is anatomic in origin. The symptoms in most cases are, to my mind, caused to the greatest extent by insufficient ability to enervate properly, and for this reason, while operating these conditions in cases where one can ease up on the enervation by making the muscles stronger, I am not as inclined to call as many cases operative in character as is Dr. O'Connor. There is no doubt that true imbalances, where the defect is anatomic, exist. I have seen the improper insertion, or the atrophic or hyperthropic muscle. These cases are the ones that promise most by operation, either by Dr. O'Connor's excellent method, as used by him, or by some other good method at the hands of a man practiced in it.

DOCTOR O'CONNOR (closing) — Drs. Jean and Barkan bring up the question that instances of true migraine are never helped by any eye treatment. If they will re-read that paragraph they will find that I qualify by using the word "supposedly." I am perfectly willing to make the diagnosis as I did in my cholera work in the Philippines—those that died were cholera; those that survived were not. At any rate, patients with those symptoms were often relieved. There must be a cause for what is called true migraine, and it is barely possible that it may be in the ocular apparatus.

Those who do not study out their obscure cases by prolonged monocular occlusion, in order to obtain the true muscle balance after complete relaxation of the extraocular muscles, have no idea what they overlook and are

not really qualified to properly appreciate this subject. That they "take no stock in it" does not alter the facts. It might be well to quote here the opening paragraphs from my paper on this subject in the October, 1924, number of the British Journal of Ophthalmology.

"The object of this paper is to emphasize the following points:

1. A hidden vertical deviation is the commonest cause of persistence of asthenopic symptoms after accurate correction of a refractive error and any apparent muscle imbalance.

2. A complete and accurate diagnosis of muscle imbalance, in kind and degree, can be made only by the aid of prolonged monocular occlusion. This procedure is the same to the extra-ocular muscles as mydriasis is to the intraocular and its importance can be upheld by the same line of reasoning. As absolute proof of this statement it might be well to take out from the table the twenty-three cases that showed exactly normal muscle balance before patching. In these cases the final tests, as regards vertical deviations only, were as follows (in prism degrees): 1 to 2 degrees, eight cases; 2 to 3 degrees, five cases; 4 to 5 degrees, two cases; 6 to 7 degrees, one case; 7 to 8 degrees, one case.

3. Nearly all cases of vertical deviation have a parietic foundation."

After nearly six years' experience with monocular occlusion, I can state positively that I would feel perfectly helpless without it in the study of those obscure cases that "go the rounds," many of whom are emmetropic and many more, as shown in the above quotation, show normal muscle balance. On the surface, in such cases, the eyes could not have been at fault and yet the prism correction, of the deviation found, gave relief.

In Doctor Barkan's comment on the muscle conditions I think he has put the cart before the horse. My whole paper argues that the symptoms are the result of overwork of the innervational circuit, but maintains that it is the anatomic changes that make this overwork necessary. At any rate, it is perfectly certain that if non-operative treatment fails to help these cases, altering the anatomic conditions is the only way out. I freely admit that we find many cases of marked muscle imbalance and no symptoms the same, as we find marked refractive errors and no symptoms. In such cases anything that reduces the general endurance is apt to reduce the local. It is for this reason that people often date the occurrence of cross-eye to some general disease like measles or whooping cough, thinking the disease is the actual cause.

In all my writings I have emphasized the importance of operating to relieve symptoms, not merely to alter measurements. For this reason I take great pains, by monocular occlusion and in other ways, to prove that the muscle imbalance found is the cause of the symptoms. Only in that way can I persuade myself that the symptoms will be relieved when the imbalance is corrected.

The fact remains that there are many cases of muscle imbalance that are not relieved by any or all of the non-operative methods of treatment. If the advisor of such a patient is not prepared to perform a safe operation on the muscle at fault, what is he going to do about it? Some years ago Doctor Barkan admitted to me that he would give up in a case of 12 to 14 degrees vertical deviation. If he had more confidence in operative work he would not have to give up. I have corrected many such cases from 5 to 40 degrees. The lower cases were most comfortable with prisms, but preferred operation to wearing glasses.

In handling cases of muscle trouble we must keep in mind that people want to use their eyes. The securing of relative comfort by not using them is a poor way out of the difficulty. Witness the patient mentioned in the body of the paper who had to give up his course in law because his previous advisors failed to perform the right operation. I am not satisfied unless I succeed in obtaining comfort in all uses of the eyes. Needless to say I am not always satisfied, but my "batting average" increases in proportion to my ability to make an accurate diagnosis so that the right treatment can be applied at the right place.

Finally, I wish to thank the discussors for their very kind and complimentary consideration of my paper.

THE TREATMENT OF CHRONIC ARTHRITIS

By LEONARD W. ELY, M. D., *San Francisco*

In the first place I have never seen a case of arthritis which was not caused by infection or by trauma, or rather I have never seen any evidence of the operation of any other cause. This gives us our first classification into traumatic and infectious arthritis.

IT WOULD be hard to find a subject in medicine about which more diverse ideas are held than the one which I have chosen. Those who regard an arthritis simply as a swollen joint, without appreciating what is going on inside of it, usually fall back upon pure empiricism, and drug their intelligence with such terms as "disturbed metabolism," "uric acid diathesis," "pars minoris resistentiae," and the like. Their treatment changes from month to month. This represents an anomaly in modern medicine, but is common practice. Usually what is practiced today is thrown away tomorrow. The things which last are established by patient investigation and the accumulation of concrete facts. The interpretation of these facts is sometimes a matter of personal opinion, and must be proved out by clinical investigation.

Some years ago, spurred thereto by the barrenness of results under older methods of handling cases of arthritis, I began to collect specimens of diseased joints, to study them in the laboratory, to compare my findings with the clinical history, and to try out in the clinic the conclusions based on my laboratory findings. It has been an illuminating and profitable experience for me, has brought order out of chaos, and has saved me the trouble of investigating for myself every new and fantastic therapeutic claim that has been made upon the sole authority of its originator's clinical opinion.

Not to be verbose, let me set forth a few of my findings, and their application: In the first place, I have never seen a case of arthritis which was not caused by infection or by trauma, or rather I have never seen any evidence of the operation of any other cause. This gives us our first classification into traumatic and infectious arthritis.

Traumatic arthritis—The joint is lined by two tissues—the synovial membrane and the cartilage. To traumatize it we must injure one of these two tissues, or both. It is doubtful if an isolated injury of the articular cartilage ever occurs, without damage to the underlying bone, though the intra-articular cartilages themselves may be torn. If it does occur, it is without effect on the other joint tissues.¹ If the ligament is torn with its subjacent synovial membrane, we have a sprain. The same thing occurs when the intra-articular cartilage is torn. If an injury damages the bone under the articular cartilage, we have an intra-articular fracture. I think perhaps some confusion has arisen from our looseness in the employment of terms. We speak of traumatizing a joint, without any definite idea of what we mean.

The effects of a sprain, not repeated, are over in a short time. The treatment of a sprain does not concern us here. With an intra-articular fracture, the resulting arthritis is probably caused by the effusion of blood into the joint, and, if accurate adjustment of the fractured surfaces be obtained, subsides slowly. If any deformity persists, then the joint is to be viewed as a damaged machine, easily sprained, and often the seat of an arthritis, unless it be kept quiet.

While more or less difference of opinion exists as to details, the treatment of these traumatic arthritides is fairly standard. It is when we come to the class of cases not caused by a frank injury of the bone or the synovial membrane, that we embark upon a sea of confusion. Examining specimens in the laboratory, I find that they all fall into one of two great groups or types, and in order not to describe them by names that next week must, with increasing knowledge, be thrown overboard, I call them Types 1 and 2. This classification can be carried into the clinic, and can be made to work. It is a help in treatment rather than a hindrance. Many classifications have been proposed, some so complicated that they can hardly be remembered by anyone but their author. Type 1 are, as a rule, the more active inflammations. They are characterized, primarily, by a proliferative inflammation in the bone-marrow or in the synovial membrane, or in both. They are recognized clinically by the absence of any spurring or lipping, as revealed by the x-rays. In Type 2 cases, these bony spurs are present.

The cases in Type 1 are the frankly infectious cases, and include the bacterial arthritides. Among them are tuberculosis, syphilitic and typhoid arthritis, coccidioidal granuloma, and the arthritis presumably caused by the diplo-streptococcus domiciled in the deep urethra or in the tonsils.

As the fundamental pathological feature of all these cases is the same, it follows that the clinical picture and symptomatology of them are alike. Each of them has its peculiar features which enable us to make a fairly accurate guess of its nature, but an exact differentiation can be made only by the identification of the causal organism. To enter into the details of the differential diagnosis would take us too far afield. Only their treatment can be discussed here. This classification includes those arthritides due to a so-called focal infection. The presence of a primary focus is admitted by practically everyone in the case of tuberculous and syphilitic arthritis, though some deny the influence of the diplo-streptococci domiciled in the tonsil and deep urethra in the other cases. It follows, therefore, that there is at least an approach to unanimity in the treatment of the first class, and great difference of practice in the second.

TREATMENT OF CASES OF THE FIRST TYPE

Tuberculous Arthritis—Uncomplicated tuberculosis of a joint is in itself a comparatively harmless though severe disease, and is strictly confined to the synovial membrane and bone marrow, damaging the other tissues in and about the joint only by interfering with their nutrition. Its presence, however, shows the presence of a primary focus elsewhere in the body, as well as a lessened consti-

¹ Ely & Cowan, *Bone vs. Joint Studies*. 1. Stanford University, 1916. Published by the University.

tutional resistance to tuberculosis. As far as the patient is concerned, the final outcome will depend upon his resistance to tuberculosis. When a secondary infection is added, tissues other than the synovial membrane and lymphoid marrow become vulnerable, and instead of a strictly localized, comparatively harmless disease, we have a widespread and very serious one, with all the dangers of a pus infection added. The presence of lymphoid marrow and synovial membrane in and about the joint is dependent upon function. When function is removed from the joint these tissues tend to disappear. When they disappear the disease dies out. From these facts we draw the three primary rules for the treatment of tuberculous arthritis: (1) Deprive the joint of function. (2) Avoid secondary infection. (3) Build up the patient's nutrition and his resistance to disease.

Coccidioidal Granuloma—The treatment of this form of arthritis is very much the same as that of tuberculosis, but not nearly so satisfactory. The outcome is almost invariably fatal.

Syphilitic Arthritis—The treatment is the same as that of syphilis of any organ, and consists of neoarsphenamin, mercury, and the iodides. Operation should be sedulously avoided on account of the almost invariable tendency of the wound to break down and become secondarily infected. Secondary infection makes the treatment much more difficult. Parenthetically, the necessity of ruling out syphilis in the treatment of any case of first type arthritis, especially in the operative treatment, should be urged. To discover afterwards that one has been operating unnecessarily upon a syphilitic joint, is always humiliating. I know of but one safe way to rule out syphilis, and that is by a course of anti-syphilitic treatment.

Typhoid Arthritis—Little need be said of the treatment of these cases. They are to be handled on general principles. Apparently, most of them recover with treatment or without it.

OTHER CASES IN TYPE 1

Because the cause of these cases never has been proved, great difference of opinion prevails as to their nature and as to their treatment. From some of them pure cultures have been obtained of a bacterial organism, variously named diplococcus, diplostreptococcus, streptococcus viridans, etc. From many of them all attempts to obtain cultures have been in vain. They are usually multiarticular. I think that most of them are caused by bacterial organisms domiciled in some other organ, and brought secondarily to the joints, fed to the joints, so to speak. This belief rests not only on the fact of their frequent cure after the removal of the primary focus, but also, and principally, on the practically identical changes in the morbid anatomy of these joints and in that of those arthritides known to be caused by bacterial organisms.

Following out this theory, our best results have been obtained by the removal of the presumptive focus. In no instance that I remember have we found this focus elsewhere than in the tonsil or in the deep urethra. I think that infection in the alveolar process of the jaws is never responsible for this

form of arthritis, but always for the second type. When the presumptive focus is removed many of these cases recover, with other treatment or without it. Those of them which did not, I had grown accustomed to regard as practically hopeless, but Dr. Barrow of Los Angeles has almost cured one of my apparently hopeless cases by eradicating intestinal parasites, and his success has opened up a new field which we are cultivating, with promising results. Ordinarily, one or two recoveries are a poor foundation on which to build a line of treatment, but those of you who have had the opportunity to treat patients with this form of multiarticular inflammation know that they do not recover spontaneously. They may have remissions and temporary improvement, but when they become bedridden they stay so.

TREATMENT OF THE SECOND TYPE OF ARTHRITIS

I have published so much on this type of arthritis in the past few years that I shall merely give my results to date. This is the form of arthritis characterized by the presence of bony and cartilaginous outgrowths in the region of the attachment of the capsule. It is variously named by different writers as hypertrophic arthritis, degenerative arthritis, osteoarthritis, arthritis deformans.

Further investigation has confirmed the belief that the prime pathological feature of this form of arthritis is an aseptic necrosis in the bone in the region of the joint. All the other pathological features are secondary to this. The presence of these necrotic areas can often be detected in the x-ray films, if it is sought. All the morbid changes in the bone and marrow are so different from those caused by bacteria that it is impossible to believe that bacteria cause the disease, and yet when one studies specimens in the laboratory, one cannot but be positive that the changes in them could be caused only by a living organism. This is the chief reason for my firm conviction that some form of animal parasite is responsible for the disease, and the probable culprits are the intestinal protozoa. It must be confessed that up to date we have no reliable proof of their presence in the bones. The evidence is purely circumstantial. I believe that the amoeba or a similar organism is responsible for these aseptic areas in the bones, for the same reason that if I should see a little pile of dirt in the field with a depression in the center of it, I should think that a gopher was responsible for it. This is just the sort of lesion that the protozoa might be expected to cause if they gained access to the bone-marrow.

With the co-operation of Doctor Harry Wyckoff of the Stanford Laboratory, a routine examination of the stools of our patients suffering from this form of arthritis has been conducted. Parasites have been found in about 30 per cent of the cases. Amoeba coli has been found most frequently; giardia, chilomastix, histolytica, and trichomona less frequently.

As heretofore noted, infection in the alveolar process of the jaw is present in an overwhelming proportion of these cases. The rational theory of the pathogenesis of the disease would be that some form of protozoon, possibly harmless while domiciled in the gastro-intestinal canal, gains access

to the circulation through the diseased bone at the roots of dead teeth. It is then carried to the bone marrow, and causes necrosis. Perhaps we shall find that the so-called harmless amoeba gingivalis is to blame. I strongly suspect that this is the case.

In the orthopedic clinic at Stanford we have conducted the treatment of these cases according to this line of reasoning, and our results have been, on the whole, good. The first step in the treatment is to remove all dead teeth, which serve to keep open the door in the bone of the jaws. Next we institute a search for intestinal parasites. If they be found, the patient receives the full parasiticide treatment, namely, neoarsphenamine, emetin and ipecac; if not, then emetin and ipecac are administered without the neoarsphenamin. A short time ago we set aside one day in the week in the clinic for the special treatment of patients suffering with second type arthritis.

The problem of the treatment of an inflammation in a joint should be approached in the same manner as that of the treatment of any other organ, but, strange to say, it rarely is. This is the main burden of my thesis. The intelligent medical man, when called on to treat an inflammation in the lungs, does not waste time talking about disturbed metabolism, the rheumatic diathesis, or mysterious humors floating in the blood. He does not try gland therapy, rub things on the skin, or primarily administer drugs internally. He tries, first of all, by clinical examination and laboratory tests, to establish to his own satisfaction two things: First, what is going on in the lungs (the pathology), and second, the cause of the inflammation. I submit that the same procedure is necessary in treating inflammation of the joints. Anything else is pure empiricism.

OBSTETRICS THE STRONGHOLD OF MEDICINE TODAY *

By G. C. H. MCPHEETERS, M. D., Fresno

A plea for better, more detailed, more efficient service to every pregnant woman. This attention should begin with the little child, include the young girl at puberty, the adolescent girl before marriage, the young married woman before pregnancy, and extend throughout each pregnancy. This I conceive to be the true scope of obstetrics today.

The non-medical public will appreciate the full scope of obstetrics only and when we, as a profession, all practice real obstetrics.

DISCUSSION by A. Huffaker, Carson City, Nevada; John Tees, Reno, Nevada; Thomas A. Card, Riverside, and William A. Beattie, Sacramento.

INTRODUCTION

IT IS the purpose of this paper to present what the writer considers the broader scope of obstetrics today, as distinct from the midwifery of the past, and to outline methods which every physician may employ in the movement for better obstetrics. Mere attendance at a birth, together with one or two postpartum visits, is no longer acceptable to the public we serve. The better classes of intelli-

gent people, such as we all delight to call our patients, have learned to demand care from the physician during pregnancy. They also expect better care during confinement than midwives can give, and finally they demand postpartum care adequate to the needs of mother and baby. Patients, members of their families and neighbors are quick to check over the care given by their physician, especially so if disaster occurs during pregnancy, accident at delivery, or any unfortunate result during the puerperium. This checking of services rendered too frequently leads to censure of the attending physician, especially if his services have been thought to be half-hearted or careless. There is no class of medical work where the personal, whole-hearted attention and interest of the physician is demanded so fully as it is in obstetrics. Also there is no branch of practice where there are greater rewards for the physician's attention if he will but give it. Therefore, we owe it to our confinement patients and to the reputation of our profession of medicine to practice comprehensive obstetrics, not careless midwifery.

In this heyday of the charlatan and quack, who draw a large clientele even among former patients of the educated doctors of medicine, we are seeking means by which we may maintain the confidence of the public. This has been the subject of much serious discussion and some pessimistic writing of late years. It is the secondary purpose of this paper to present the thought that we as physicians may maintain the age-long confidence of the public in no more effective way than by the practice of thorough-going obstetrics. It is my firm belief that obstetrics is the stronghold of medicine.

PROBLEMS AND TASKS

Before stating my conception of the scope of modern obstetrics I wish to point out briefly our greatest problems and tasks. There is an annual maternal mortality of 15 to 21 thousand, and an infant mortality of about 200,000 each year in the United States, representing deaths of infants under 1 year old. It is reported by some statisticians that the United States ranks seventh among the nations in infant mortality rates, and seventeenth in the list of nations in maternal mortality rates. Some American authorities agree that very little improvement in maternal mortality rates has taken place in the United States in the last fifty years, in spite of increasing hospitalization of patients and increasing skill of obstetricians and other surgeons. Considerable improvement has taken place in infant mortality figures, due to better milk and medical attendance for infants and children. I believe the chief explanation for a high maternal and infant mortality in the United States is because the medical profession has not taught the public the value of prenatal care and adequate confinement care. Every physician should be a teacher within his circle of influence, instructing women that they must be physically fit before entering pregnancy, that they need a physician's care all during pregnancy, and that they should have careful supervision for themselves and their infants during the lying-in period and the months following. We should teach our patients that the birth of a baby is a major surgical operation as important as any, often more serious than many, and that

* Presented at the annual session of the Nevada Medical Association, Reno, September, 1924.

the results of a poorly conducted confinement often affect the health of the mother for the remainder of her life.

SCOPE OF MODERN OBSTETRICS

I will now outline what I believe to be the scope of modern obstetrics, as distinguished from the midwifery practiced in former generations and still being practiced by some physicians apparently indifferent to the valid claims of the pregnant patient. Obstetrics contemplates the woman when she was a little girl, since the health of the mature woman is often determined by the health of the little girl. Examples are legion, a few only are needed to make our point clear. The nephritis and pyelitis of infancy and childhood is now known to be far more common than was formerly suspected. This infection of the renal system in childhood often persists through adolescence and damages the female kidneys for life. We have the resulting nephritic type of gravida who, too often, comes to grief before term. Again, the tuberculous child becomes the tuberculous mother, who is a danger to herself, her child, and her husband. Again, we have the anemic, marasmic little girl with neglected focal infections who has imperfect, retarded physical development at puberty and during adolescence. This girl becomes the thin, nervous wife, eager to do her part as a mother, but doomed to failure so often, even with all the skilled aid we can give her. We physicians should teach the mothers who are rearing little girls the value of frequent examinations of their children, and the special problems incident to puberty in young girls.

Obstetrics today contemplates also the pre-nuptial examinations of all girls and women to determine their fitness for marriage. Some states require the physical examinations of both parties intending marriage. Physicians should instruct parents to appreciate the advantages of physical examinations, of their daughters especially, before marriage. At such examinations the careful physician can discover neglected foci of infection in teeth, tonsils, nasal sinuses, middle ear, cervical glands, cervix uteri, and anal margins. He can estimate anemia, discover bacilluria and pyuria. He can discover serious malpositions of the uterus, cysts of the ovaries, which sometimes exist before marriage, varicose veins, and contracted pelvis. He can demonstrate the daily afternoon temperature, which may mean incipient tuberculosis or pyelitis. Lastly, he can perform the Wassermann test, which should always be done before marriage.

Again, obstetrics today employs the thorough physical examination of all married women, before each pregnancy if possible, or at least early in every pregnancy for the same reasons that we examine the girl before marriage and for additional reasons. We should know whether the wife or expectant mother has acquired any foci of infection since her marriage, whether she is anemic and underweight, whether nausea of pregnancy exists, and whether syphilis or gonorrhoea is present. If not examined prior to their marriage, the examiner will find much to be done for about 75 per cent of all expectant mothers whom he examines.

Obstetrics further embraces the systematic pre-

natal care of every gravida who presents herself at any period of pregnancy. This care begins with the head-to-foot examination above spoken of, including blood and urine tests and pelvic measurements. A careful history and complete record of findings must be kept. Time should be taken at the patient's first visit to instruct her in caring for her person in any ways you see are needed. Tell her how to obtain the suitable publications of "prenatal care," "infant care," and "child care." Give each patient your own outline of instructions, plainly typed or mimeographed. These instructions should cover the hygiene of pregnancy, frequency of visits to your office, urine tests required, diet directions, and care of the excretory function. A list of danger signals should have a place in our written directions to an expectant mother, such as edema, scanty urine, fainting, dizziness, showing of water or blood, and the positive direction to notify you if any such occur.

Show the pregnant patient at her first visit that you really are deeply interested in her welfare, and then maintain that interest at the succeeding visits to office, or home. Encourage each patient to tell you how she feels. Symptoms she considers trivial may mean the pre-eclamptic state to your trained mind.

Prenatal care includes the eradication of all focal infections as far as possible, without regard to the presence of the pregnancy. Abscessed teeth should be extracted, infected tonsils removed, nasal catarrh actively treated, nasal sinuses drained, anemia corrected, lacerated, eroded cervixes treated, and bacilluria and pyuria relieved, even if cystoscope and ureteral catheter are needed to do so. As physicians we must use our influence to correct the ancient hearsay that a pregnant woman may not safely have done any treatments or operations needed.

Prenatal care embraces also the regulation of the patient's diet, especially during the latter half of pregnancy. Patients not instructed about diet often gain forty to sixty pounds during a pregnancy, and their babies often reach nine pounds or more at term. Babies of this size often cause dystocia, prolonged labor, inertia uteri, forceps delivery, perineal and cervical lacerations and Caesarean sections in women whose pelvic measurements are normal and who might have delivered an average-sized baby naturally. I do not contend that we can regulate the size of the baby at birth by diet directions in all patients. Large women with large husbands, and sometimes small women with large husbands will continue to produce large babies, in spite of diet regulations. In general, however, the healthy gravida should gain not to exceed thirty pounds while pregnant, and her baby should weigh seven and one-quarter to seven and one-half pounds at birth. Diet for the latter half of gestation should be poor in starches, sugars, and fats, while bulky with vegetables, fruits, milk, fresh fish, eggs, a little lean meat, and cheese. This diet relieves the bowels, kidneys, skin, and respiratory system of much work in elimination.

One of the refinements of prenatal care in recent years is the instruction of pregnant women in the care of the abdomen and breasts so as to preserve the contour and profile. The patient may prevent striae gravidarum by a simple system of daily mas-

sage of the skin of her abdomen.* Also proper massage of the breasts during pregnancy will preserve their contour throughout lactation. After the period of lactation is over, patients may so care for the breasts as to restore contour, firmness, and tone.

During the period of prenatal care the physician should discuss arrangements for the confinement. Make your patient see the importance of hospitals and lying-in homes as best for her and baby. If confinement must be in the patient's home, be sure proper arrangements can be made for delivery there. Above all, be sure your patient has a competent nurse, or experienced, reliable attendant. Do not be satisfied with confinements conducted in midwife style. Watch details and the delivery will be an orderly success, not a nightmare for the patient and a struggle for you.

Go to your patient promptly when she calls you. She may not need you, but your prompt response assures her of your continued interest. Examine the abdomen and make a rectal examination—never a vaginal examination—at this first visit. If the patient does not require your aid for some time, you may go away. But instruct the nurse or other attendant to summon you when pains are more severe, or when other evidences of second stage begin. Plan to be with the patient, actively assisting her during the last two hours of labor. The doctor who wishes to be called when the head is visible on the perineum and who rushes out (like a fireman, or police patrolman to his duty) to catch the baby and tie the cord is no better than a midwife. The ideal thing is for the physician to remain with the patient, assisting her during the whole labor. This is my practice.

Such service is remembered with gratitude by the patient as long as she lives. Such a patient will recommend her doctor to many of her neighbors, relatives, and friends. Patients who have profited most by your care will recommend you most often, and you in turn will profit most on account of those patients whom you have served the best.

Speaking of the confinement again, we should instruct the patient in the first stage of labor to avoid holding the breath and straining during uterine contractions. Patients use up their reserve strength in this way before the second stage begins. When we finally put them on the delivery table and instruct them to bear down with each contraction we find them weak, or perhaps we have an actual inertia uteri. Many such patients require forceps delivery who might have delivered naturally with better management from the start.

Patients in labor should be kept in bed, except those rare cases where uterine contractions cease when the patient is lying down. The position in bed should be flat on the back, with the knees drawn up and the feet apart so that the knees support each other naturally, or else with a thin pillow under the knees so that the lumbar curve of the spine flattens out on the mattress. The patient should be instructed to continue breathing during uterine con-

tractions and to relax muscles, letting the uterus alone contract. Patients who are highly nervous and unable to relax, and those who persist in straining during the first stage pains should receive codeine sulphate gr. $\frac{1}{2}$, or morphine sulphate gr. $\frac{1}{8}$ to quiet them. If these doses are not sufficient in any given case, we repeat either dose one hour later. Patients should void urine each hour during the first stage of labor. This reduces the number of parturients who have bruised, irritable bladders, and who may require the catheter after confinement.

We should not place our patients on the delivery table, as a rule, until rectal examination shows dilatation of the cervix is complete. Not until then do we offer any anesthetic, and then only do we permit the patient to hold the breath and bear down. Nearly all patients have sufficient reserve strength to complete their delivery naturally with proper assistance. After delivery we choose to give our patients obstetrical pituitrin $\frac{1}{2}$ cc. in the muscle of the front of the thigh. We believe this hastens separation of the placenta, and so contracts the uterus that we have diminished bleeding when the placenta is born. A second injection of 1 cc. pituitrin should be given deep in the thigh muscle one hour later, before we leave the patient. Ergotone may be used, but it is more irritating and less reliable.

Routine examination of the hearts of both mother and baby should be made one hour after the birth. Also after other routine attention to the infant we administer 5 cc. maternal blood subcutaneously in the abdominal or chest wall. This increases the coagulation time of the infant's blood and thus combats cerebral and other internal hemorrhages, if such exist. We repeat this injection of maternal blood if infant shows evidences of hemorrhage later on.

CONCLUSION

In conclusion, I will leave it to your calm consideration that there is no physician who enters the hearts of his patients so deeply as the physician who attends the parturient woman. Two lives are in his hands, and the happiness of every member of the family. He is loved and trusted and revered far more than the doctor who renders less intimate services, however important they may be. Pregnancy and confinement are the supreme adventure of a woman's life, and her personal physician is an important party in this adventure. For years mothers are saying by the scores, "Doctor Jones, do I know him? Why he was the doctor who brought little James into the world!" And years later they walk into your office like strangers and wait for an hour to see you. Upon being asked to come in they say, "Do you remember this little boy, doctor?" And here is James, 5 or 6 years old. You may have forgotten them, but they will never forget you!

In summarizing, I am pleading for better, more detailed, more efficient service to every pregnant woman. This attention should begin with the little child, include the young girl at puberty, the adolescent girl before marriage, the young married woman before her pregnancy, and extend throughout each pregnancy. This I conceive to be the true scope of obstetrics today. The non-medical public will appreciate the full scope of obstetrics only and when we as a profession all practice real obstetrics. Better

* McPheeters, G. Carl H., M. D. The Prevention of Striae Gravidarum, Diastasis of The Recti Muscles, Visceroptosis and Ptoxis of The Breasts in Pregnancy. American Journal of Obstetrics and Gynaecology, Vol IV, No. 2, August, 1922.

attention to obstetrics in our practice will cut down the serious maternal mortality and the appalling infant mortality which occurs yearly in the United States. Thereby we shall have more healthy mothers and better babies. Thereby the physician will profit more who better serves his patients. Thereby all physicians will endear themselves to the public, maintaining that confidence which the profession has always enjoyed. For these and many other reasons it will be found that obstetrics is indeed a stronghold of medicine today.

DISCUSSION

A. HUFFAKER, M. D. (Carson City, Nevada)—I desire to compliment Doctor McPheeters upon his very valuable paper. It represents almost pioneer work in his line. Since the great majority of physicians practice obstetrics, a careful study of McPheeters' paper cannot fail to benefit them. It will give them ideals to which they may and should strive to attain. Though it might be conceivably difficult to secure the consent of people to some of the ideas suggested in the paper, especially that of pre-nuptial examination, it would be of great value, if such examinations could be made.

I feel that I have nothing of value to add. I commend the article highly to all physicians who practice general medicine, including obstetrics.

JOHN TEES, M. D. (Reno, Nevada)—I have read Doctor McPheeters' paper with both pleasure and profit. It is one of the most practical papers I have ever read. All I can add is to emphasize the importance of the prenatal care of the breasts and nipples, for, as a pediatrician, this point appeals to me strongly.

THOMAS A. CARD, M. D. (Glenwood Block, Riverside)—Doctor McPheeters has stressed several factors of vital importance to the general practitioner, who would give to his obstetrical patients scientific care. It is only as we follow a program of prenatal, natal and post-natal care, such as he has outlined, that we shall be able to reduce infant and maternal mortality. Too little emphasis has been placed on prenatal care in the past. More and more we are realizing that such care prevents weakened organs from breaking under the strain of pregnancy. That the patient in labor is entitled to skilled care goes without question. Accidents of labor are bound to happen and the presence of the obstetrician may mean the difference between a happy family and a tragedy.

While I agree with McPheeters that the use of morphine and its derivatives during labor may be of value, yet great care must be exercised that its administration does not come too close to the time of delivery. The use of nitrous oxide and oxygen during labor is to be commended. It may be safely used during the first stage as well as second stage. Nitrous oxide and oxygen has proved a boon to women in labor and in my opinion should be used more extensively.

WILLIAM A. BEATTIE, M. D. (Peoples Bank Building, Sacramento)—Doctor McPheeters' interesting paper may be read with profit by every physician. The importance of prenatal care, as he outlines it, cannot be overestimated. Every doctor, to whom an expectant mother has intrusted herself, should take time to carefully outline a detailed prenatal program.

I am also pleased to read that McPheeters has emphasized the fact that every delivery should be considered a major surgical procedure. With this conception in mind, every possible means of contamination or infection should be avoided. Most strongly do I emphasize the importance of making no vaginal examinations during the progress of labor. Rectal examinations are safe, and the necessary information as to the progress of labor can be as readily determined by this method as by the former.

In conclusion I wish to add that I believe it to be the important duty of every physician practicing obstetrics, to make a careful physical examination of the mother about six weeks after the delivery.

DOCTOR MCPHEETERS (closing)—I desire to thank Doc-

tors Huffaker, Tees, Card, and Beattie, respectively, for the very kind comments on my paper.

In reply to Card about the use of morphine and its derivatives during labor, I would state that I never use these during the last two hours of labor, but rather in the beginning when dilating pains are so distressing to the patient. The use of nitrous oxide and oxygen is ideal for delivery, but still impractical for most general practitioners.

I commend Beattie's point in making a physical examination of every mother about six weeks after delivery. This is my custom also. Much unnecessary invalidism results from cervical lacerations. Malposition of the uterus might be prevented, if each mother had such an examination.

In conclusion I would say that it is my firm belief if we will all practice better obstetrics the medical profession will retain its high place in the esteem of the public.

OPERATIVE TREATMENT OF ABNORMALITIES OF THE FIFTH LUMBAR VERTEBRA

By ALFRED EDWARD GALLANT, M. D., AND
WALTER C. S. KOEBIG, M. C., Los Angeles

DISCUSSION by E. W. Cleary, San Francisco; C. B. Bennett, Berkeley; S. Nicholas Jacobs, San Francisco; H. D. Barnard, Los Angeles.

MUCH has been written about the subject of low back pain, from various standpoints.

Our contribution is a presentation of certain observations relative to the occurrence of sacralized transverse processes of the fifth lumbar vertebra and the operative technique for the removal of the same. Every orthopedic surgeon is familiar with the occurrence of these abnormalities in the course of examinations of the low back and pelvis. It is an admitted fact that sacralization of the transverse processes of the fifth lumbar can be the source of many symptoms in the problem of low back pain, although the textbooks dealing with orthopedic and spinal surgery have treated the subject quite superficially. It is only during the last few years that any serious attention has been paid to the symptomatology and operative measures concerning lesions produced by these sacralized processes.

That this peculiar abnormality of the fifth lumbar vertebra is quite common was strongly emphasized by O'Reilly when he described the various shapes of these transverse processes. In a symposium on low back pain from an orthopedic, gynecological, urological, neurological, and anatomic viewpoints, Davis casually mentioned that it was possible for these abnormal processes to be the cause of pain. Galloway, in a discussion of a paper by Fasset, told of his experience with an operation on the transverse processes of the fifth lumbar vertebra. Wright reported unsatisfactory results following an operation for the removal of an impinging transverse process of the fifth lumbar vertebra. Goldthwait showed many variations of different vertebrae, but made no mention of sacralized transverse processes. Straub presented a very comprehensive list of the causes of backache and admits of the condition of sacralized transverse processes, placing them in the class of congenital anomalies, where they rightfully belong.

Benassi does not ascribe a congenital origin to these abnormal processes, but stresses the fact that possibly they may be due to lumbosacral rickets or to chronic inflammatory changes in the bony, articu-

lar and ligamentous structures already invaded by rickets, or that they may follow some traumatic condition producing pseudosacralization.

Bauman considers the presence of an abnormally shaped transverse process worthy of much consideration and to be the cause of pain in the lumbosacral region. He reported the results of twenty operated cases, nine of which were performed on the transverse processes of the fifth lumbar vertebra. Quoting from his paper: "These cases are presented to emphasize the frequency of transverse process lesions as a cause of definitely localized pain in the back, with accompanying lumbosacral neuritis." In this paper there is a photographic reproduction of a very beautiful dissection of the nerve and bony structure of the lumbosacral region, showing very clearly how a lesion in that region can produce pain when there is a disturbance due to fractures, arthritis, or other causes.

Willis presents a very interesting study of the subject of vertebral anomalies, but does not dwell very much on the sacralization of the fifth lumbar, although he discusses the removal of these processes with and without good results.

ETIOLOGY

Piersol attributes this abnormal condition to an excessive development of the costal element either on one side or the other. True as this statement may seem, the question why this abnormal development takes place still remains unanswered. There was no explanation of this phenomenon of sacralization in any of the papers examined.

We admit the congenital development of this abnormal condition and wish to offer an acquired cause which takes place later in life and may be due to pathological causes or fractures.

In reviewing the writings of the various authors mentioned, with the exception of Benassi, there does not seem to be a clear differentiation between an anatomic and a roentgenological classification of these abnormal processes.

Sacralization, according to Benassi, in an anatomic sense, is the existence of surface contact between the two or three bony structures, which will be later mentioned, is quite distinct from sacralization in roentgenographic or clinical parlance, i. e., abnormal narrowing of the iliolumbosacral space, with resultant formation of more or less complete supplemental foramen, and this latter type is designated by him as pseudosacralization. Benassi's classification is as follows:

1. True or complete sacralization in which there is articular contact on the surface or else complete bony fusion of the fifth lumbar with the sacrum and ilium, with the formation of a supplementary foramen.

2. Incomplete sacralization when the union occurs only with the sacrum.

3. Pseudosacralization, which means that there was originally a large process which later, due to pathological changes such as calcification or thickening of the ligamentous structures, irritative exostosis, trauma producing an osteoperiostitis, fracture, possible rotation of the fifth lumbar vertebra with the production of an irritative hypertrophy of the end of the transverse process or possible bursitis.

These sacralized processes may be either unilateral or bilateral. When we consider the etiology of the pain produced by these three divisions of sacralization, it will be necessary to consider the mechanism of the lumbosacral region in order to make our point clear. In viewing the lumbosacral region from an anteroposterior position, we are able to see the presence of these abnormal processes and their relationships; yet we think it better to consider this region laterally or in profile. You are all familiar with the shape of the lumbar curve and the relation of the fifth lumbar vertebra to the sacrum in this curve. We find that the fifth lumbar vertebra lies below the highest point on this curve which we placed between the third and fourth lumbar vertebrae. The body of the fifth lumbar vertebra points somewhat downward, and with any type of sacralization it is safe to assume that a lesion can be produced when there is a disturbance between either the fifth lumbar vertebra, sacrum or ilium, granting that with an incomplete sacralization of the fifth lumbar vertebra on one side or the other and with a rather high or prominent projection on the wing of the sacrum, it is possible to have a lesion produced when sufficient force causes that incomplete sacralization to change its relationship to the iliolumbosacral space, either by ligamentous strains or tears or fractures. In completely sacralized transverse processes trauma may play a part in fracturing one or both of these processes, and with the advent of callus formation the iliolumbosacral space may become narrow in its diameter, involving the ligamentous and nerve structures which are in close relationship to the parts affected. When there is a unilateral complete sacralization it is possible to disturb the sacroiliac joint on the opposite side, and we have seen several cases where this phenomenon has occurred. Such conditions as scoliosis, lordosis, congenital defects of the spinous processes of the fifth lumbar vertebra aid in producing a lesion when there is either a unilateral or bilateral sacralized transverse processes.

Of all the papers examined, Benassi is the only one who makes allusion to the iliolumbosacral space, which is a very important factor in this problem.

As a final consideration of the mechanism of the pain produced by this abnormality, Moore says it is due to the following:

1. Pressure on the soft parts (muscles or ligaments) between the transverse process and the ilium.
2. Irritation or arthritis of abnormal bursae or joints.
3. Strain of the sacroiliac and lumbosacral joints, due to leverage of the transverse process.
4. Stretching or pressure on the nerves of the lumbosacral plexus.

These reasons, as given by Moore, are perfectly logical and can be demonstrated in a study of the radiographs, in which there is sacralized transverse processes. Before turning to the discussion of the symptoms, we admit that it is possible to have sacralized transverse processes without symptoms, yet the symptomless conditions are, without doubt, potential elements in the production of lumbosacral pain if the relationship of the structures in this re-

gion are disturbed. Traumatism is an important factor in the history of these conditions. Many patients who come seeking relief from low back pain, lumbago, and sciatica give a history of gynecological and abdominal operations without relief of symptoms show these abnormalities when examined with the x-ray. There is no age limit specified by any writer when one can expect trouble from these abnormalities.

SYMPTOMATOLOGY

Gordon places lumbosacral pain as the most conspicuous symptom. This pain may be unilateral or bilateral. In unilateral cases it may sometimes be referred to the opposite side, but its greatest intensity is on the sacralized side. In bilateral cases the pain may extend to the knees or ankles, producing a terminal neuritis at the distal portion of the sciatic nerve. Changes in the standing or sitting postures may aggravate this pain. There is a characteristic attitude of standing and walking so that the patient may list to one side, similar to that posture sometimes found in sacroiliac disturbances. There may be an asymmetry in the sacro-iliac region and a possible scoliosis in the lumbosacral region when there is a unilateral transverse process. The lumbosacral pain may sometimes be chronic or intermittent and aggravated by such twisting movements, playing golf, or attempting to reach upward. This pain may follow the course of the anterior crural, obturator and superior gluteal nerves, or it may be confined locally to the region of the transverse process. There may be an atrophy of the muscles of the leg of the affected side in severe cases. The sacroiliac region may show no pain, but there may be definitely localized pain just about this region. Lastly, a history of lumbosacral pain at night, due to a neuritic or arthritic lesion in this region, may be elicited.

EXAMINATION OF THE PATIENT

The physical examination should be made with the patient stripped and careful attention paid to the movements of the spine in the region of the lower back, and also to the postural attitude of the patient. Anteroposterior stereoscopic and lateral roentgenograms of the lumbosacral and pelvic regions should be made.

DIFFERENTIAL DIAGNOSIS

Under the head of differential diagnosis, one must consider faulty posture, lumbar scoliosis, spondylolisthesis, osteoarthritis, lumbar Potts' disease, sacroiliac disturbances, flatfeet with secondary back strain, hyperthropic arthritis in the region of the hip-joint, and the presence of old fractures of the articular processes of the fifth lumbar vertebra.

Owing to the limited amount of time allowed, it will be necessary to cover a large amount of ground in a few words. The operation, as we have modified it, seems to present very few difficulties, and in our opinion is as safe as the ordinary abdominal operation. We have seen a large number of cases treated by conservative measures over periods of years, and we feel that the removal of the process is justifiable where these measures have failed to give relief.

The method of exposure must be determined from

information furnished by stereoscopic x-rays; this not being available, a number of oblique x-rays, taken from different angles, must be read.

There are several skin incisions advised by other men, but we feel, after trying modifications of them all, that an incision beginning one and one-half inches above the center of the crest of the ilium, curving backward at the same distance above the iliac crest and ending at the second prominence of the sacrum in the midline fulfils all requirements. The incision is carried through the superficial fascia, and the flap is laid back laterally by knife dissection. After controlling hemorrhage, which is easily done, an incision is made through the lumbar-poneurosis along the crest of the ilium down to the bone, from about two inches above the posterior-superior spine to one inch below it. The lumbar muscles are reflected subperiosteally until the transverse process is reached. The retractors are then inserted into the wound, and the transverse process is brought into the field by pushing the muscles toward the midline.

As will be seen from the slides presented, the operation is easier in the female type of pelvis than in the male type, because the transverse process of the fifth lumbar vertebra is more nearly on a level with the crest of the ilium and the space is greater. In the male type of pelvis, it is usually necessary to strip the gluteal muscles and remove a segment of bone two inches long by one inch wide from the ilium at level of the process, making the approach easier (after the manner described by Beveridge H. Moore, in "Joint and Bone Surgery," April, 1923). We have operated on one case where the pressure of the transverse process against the ilium was great enough to push this bone segment one-quarter inch, or more, laterally as soon as it was freed. The process having been exposed and the posterior border having been cleared of soft parts, the wound is packed with hot saline gauze to check the oozing.

Formerly, it was our custom to remove the transverse process subperiostially and then remove as much of the periosteum as possible afterwards. This was very difficult and was followed by untoward results in one case, the patient having a haematoma, which caused paralysis of the anterior crural nerve. Fortunately, this condition has almost entirely disappeared.

It was suggested by one of our associates that the transverse process be removed, together with the periosteum, by freeing the process from soft parts with the finger, while the hands of the assistant were held on the muscles of the thigh, to give warning when the nerves were being impinged upon. The slight pressure of a blunt instrument, or finger, on the nerve containing tissue will immediately stimulate the nerve and cause muscle contraction. In this way, our assistant can tell us exactly of any nerve impingement. Since we have adopted this method of procedure, we have had no trouble in removing the process, nor have we had any untoward results.

After the soft parts are carefully stripped from the periosteum with the finger, the iliolumbar ligaments attached to the front lower part of the process must be freed with scissors. In our opinion, this is the dangerous part of the operation, as it is in rela-

tion with the psoas major in front, and it is in this muscle, at varying depths, that the nerves and blood vessels most easily damaged run. We have found it advisable to put the finger down, above and in front of the process and, after freeing the soft parts in this location, to take a sharp osteotome and sever the process vertically in its mesial one-third. This must be done very carefully. Where the sacralization is of the true type, it is necessary to free either iliac or sacral attachments and then, with the careful use of the Mayo scissors, the iliolumbar ligament is severed after carefully testing each portion of the tissue with the blunt point of the scissors or Brisco coil.

Following the untoward result mentioned above, we became very cautious and decided that it might be possible, in some cases, to enlarge the iliolumbar sacral space in complete sacralization by simply chiseling off the lower border of the enlarged process and not removing the process. While the case thus operated upon has been entirely free from symptoms for over a year, x-rays taken at the present time are showing a bone regeneration, and we believe it will only be a matter of time until the symptoms again appear. It will be interesting to note at this particular time that this patient sustained an injury seven years ago while lifting cannon during one of the numerous Servian wars, and has had symptoms such as Dr. Gallant mentions ever since, although he was treated by several of the best orthopedic surgeons on the continent and in the United States. In addition to the above symptoms, he had a complete loss of sexual function. Following the operation, his pain entirely disappeared in four days and the sexual function has been slowly returning.

The closure is made by stitching the edges of the periosteum together over the crest of the ilium with No. 2 chromic catgut. Where a segment has been taken out of the ilium, it may be replaced. The skin is closed in the usual manner, with a drainage tube through the flap to prevent pressure from bleeding.

The after treatment consists of rest in bed. A plaster paris jacket, which is left on for two weeks, or the Bradford frame may be substituted if the patient is very heavy. Following this, a Taylor brace or leather corset is worn for four or five months, as a matter of protection. Physiotherapy is started as soon as possible. The last four patients we operated upon were able to leave the hospital, with a brace and walking, on the tenth day, free from all pain.

In conclusion, we would say that:

1. The incidence of sacralized transverse process of the fifth lumbar vertebra is more common than has been supposed.

2. It is possible to have a symptomless enlarged transverse process, or an enlarged transverse process may give symptoms early or late in life.

3. An enlarged transverse process may give no symptoms until a jolt, or other injury, is sustained.

4. Changes in the relationship of sacralized transverse process can produce pain which has been incorrectly diagnosed.

5. After conservative measures have failed, we

feel that removal of the transverse process is justifiable.

6. The technique described should give uniformly good results if carefully carried out, and the diagnosis is correct.

7. Pain disappears almost immediately following the operation, and the scoliosis, if present, in about six months.

8. We are as yet unable to draw definite conclusions as to the final outcome. The first case we operated—two and a half years ago—has remained symptomless, and the others, done at intervals, with the exception of the one in which we had the untoward result, are apparently cured. A longer period of observation is necessary to determine the final outcome.

Van Nuys Building.

DISCUSSION

E. W. CLEARY, M. D. (177 Post Street, San Francisco)—We are much indebted to Doctors Gallant and Koebig for presenting to us so ably the results of their study and experience in cases of low back pain associated with abnormalities of the fifth lumbar vertebra.

It is evident that they have been at great pains to perfect the technique of operation for removal of a sacralized transverse process and have carefully selected their cases for operation. These factors, no doubt, account for the encouraging results they have obtained.

I have seen so many cases of pain and soreness in the lumbo-sacral region in which the x-rays revealed no abnormalities of bone structure and, on the other hand, have happened upon so many instances of definite bony anomalies, in this region, in individuals who have never had a symptom or a sign of low back pain, that I have found it difficult to convince myself that the anomalous process is often the cause of the pain. It is, perhaps, for this reason that, although I have seen and have treated, conservatively, a number of cases of lumbo-sacral pain associated with anomalous transverse processes, I have not accumulated a series of operated cases.

The disability from lumbo-sacral pain is so considerable and the conservative treatment often so slow in accomplishing even indifferent results, that an operation which promises prompt and complete relief, even in a small percentage of such cases, is received with enthusiasm.

The dangers are that possible complications, through injury of important structures lying adjacent to the operative field, may be held too lightly, and that cases for operation may not always be selected with the wisdom that is indicated by the results reported in this article.

C. B. BENNETT, M. D. (1122 University Avenue, Berkeley)—The subject of the proper treatment of lower back pains is extremely important as the condition is one of our commonest ills and often one of our difficult problems. Any contribution to our knowledge, therefore, is certainly welcome. Since the lower lumbar region is quite flexible and at the same time must sustain the entire weight of the upper part of the body together with any object carried in hands or on back, it is easy to realize how slight anatomic variations, congenital or acquired, might cause considerable disability, especially as use of this part of the body is required in practically every form of activity. The importance of variations in the transverse processes of the fifth lumbar vertebra in scoliosis, back strains, sciatic nerve pains, etc., is well known. The application of body casts, back splints, corsets, adhesive strappings, together with diathermy, etc., have proven of great service, and many cases of back pains, even in the presence of sacralized fifth lumbar vertebrae have obtained complete relief by simply the correction of faulty posture. However tempting a surgical operation may appear, I think that a thorough trial of the established procedures by those competent in orthopedic work should first be attempted, as the vast majority of cases can thus be relieved. Those who, however, are not thus helped,

must of necessity turn to more radical means. I have had no personal experience with the operation mentioned here, but am much impressed with the excellent results reported, and can only hope that like results may be obtained by those following the technic given.

S. NICHOLAS JACOBS, M. D. (209 Post Street, San Francisco)—There is no doubt of the increasing importance as to the proper handling of cases showing abnormalities of the fifth lumbar vertebra and particularly those cases with sacralization, either unilateral or bilateral, showing symptoms. That it is a rather common condition, which heretofore has been quite generally overlooked, especially in those presenting themselves with symptoms of lower back strain, is well shown by the answers to several questions which I put to Doctor Howard Ruggles.

He informs me that of all cases roentgenologically examined in their offices in which the lower spine appeared, regardless of the purpose for which the examination was made, over 10 per cent showed sacralization of the fifth lumbar vertebra, either partial or complete. Furthermore, about one-half of the cases showing sacralization are so-called "pick-ups," that is, accidental discovery of the condition during routine examination, and comprise many who have not shown any symptoms referable to the lower spine. He has found sacralization quite commonly present in children as well as in adults, the youngest at three years of age and with no evidence roentgenologically in these children of a previously existing rickets, which might be considered as an etiological factor in the production of sacralization as has been claimed by some authors.

He has also found the sacralization as common or even more so in those other than working people, in whom we would more naturally expect to find, because of the nature of their work, chronic inflammatory changes in the lower spine; and this does not bear out the theory of the etiology, as claimed by other authors, as being associated with chronic inflammatory changes in the bony and articular surfaces of the lower spine.

Taking the above into consideration, it leaves little doubt as to the congenital origin of these abnormal transverse processes.

As to the indications for operation, time alone will tell us in just which type of cases we can expect relief of symptoms by operation. I wish particularly to emphasize the fact that in the presence of sacralization on one side, which produces fixation, there results an abnormal mobility on the opposite side and an abnormal susceptibility to injury which is very often the cause of a stubborn sciatica. In these cases removal of the sacralized transverse process relieves symptoms by re-establishing mobility.

H. D. BARNARD, M. D. (2417 South Hope Street, Los Angeles)—Anyone who is called upon to struggle with the problems concerned in obtaining benefit in the treatment of patients suffering with low back pain will watch with interest the results obtained by the operative treatment of abnormalities of the fifth lumbar. The very complicated nature of the etiology of these low back syndromes and the exact role which is played by these so-called sacralized conditions of the last lumbar vertebra make the treatment far from an exact science in my judgment. Definite proof as to whether these sacralized fifth lumbar are entirely causative, or only contributory, or only predisposing; whether pain is produced by inflammatory reaction as result of trauma; just what the element of nerve pressure is; just what cases develop the inflammatory bursitis between the iliac crest and the transverse processes; what the relation is between a stabilized transverse process on one side, and the normal mechanism concerned in the joint action on the other; the relationship, if any, of the forward displacements of the fifth lumbar which are being demonstrated with much more frequency; whether these abnormalities of the fifth lumbar cause sacro-lumbar trouble or sacro-iliac, or a combination of both—even these are not all of the questions which must be answered more definitely before this surgical procedure can be put on a clear-cut status where the indications and contra-indications will be generally accepted. The percentage of cases is comparatively low where it is possible to accurately diagnose the exact location of the cause of the low back pain or sciatic irritation, whether it be sacro-iliac or sacro-lum-

bar, or a combination of both, either with or without the so-called sacralization of the fifth lumbar, partial or complete. The points of differential diagnosis, while comparatively definite as described by certain authors in the literature, are far from infallible. Certain cases obviously localized beyond a question of a doubt in the sacro-iliac joint, have, in our experience, done nicely after the arthrodesis operation described by Smith-Petersen. Likewise fusion of the last lumbar to the sacrum in certain types of lumbo-sacral trouble has proven equally satisfactory in our hands.

To just what extent the resection of the transverse process of the fifth lumbar will stand the acid test of time is highly problematical in my judgment. This doubt is only made more profound when we consider the disconcerting data which each of us must encounter in our actual experiences of the variable results, both successful and otherwise, which accompany the different types of treatment for these low back conditions, a certain percentage of which must fall into the class of abnormalities of the fifth lumbar under special consideration in the above papers.

DOCTOR GALLANT (closing)—In reviewing the criticisms of the men who were kind enough to discuss this paper, we admit that this operative procedure, for the correction of the conditions under consideration, is a difficult one and should only be done in properly selected places. We feel that after all conservative measures having been tried for a sufficient length of time and failing to obtain satisfactory results that such operative measures are justifiable. We are well aware that dire results can easily follow surgical measures, particularly in the region of the fifth lumbar vertebra and sacrum and feel certain that if the technique described in this article is carefully followed the results ought to be good. We know that it is a big problem and a difficult one, especially from an industrial standpoint, and if a small percentage of cases can be relieved we still feel justified in resecting these transverse processes. We know of one instance at the Los Angeles General Hospital in which all conservative measures were employed and failed to obtain good results. This patient had a unilateral transverse process resected and four days afterward was absolutely free of pain and able to walk about the ward. His post-operative recovery was uneventful and to date has had no return of symptoms. In closing, we wish to express our thanks to the men who have so kindly discussed this paper.

FUNCTIONAL TESTS OF HEARING

By ISAAC H. JONES, M. D., Los Angeles
AND VERN O. KNUDSEN, Ph.D., Los Angeles

A discussion of present methods and the announcement of the success of the more recent Audio-Amplifier.

DISCUSSION by Frank A. Burton, San Diego; W. E. Waddell, Los Angeles; Anna B. Lefler, Los Angeles; H. G. Merrill, Provo, Utah.

IT SEEMS to me that we have a unanimous opinion on one subject—our dissatisfaction with the functional tests of hearing. It may be urged that we could do better work in our auditory tests if we were to make full use of our present available methods of testing. However, the fact remains that the records of our work in daily practice are apt to show very meager data. Perhaps this is due, not so much to a lack of interest, as a lack of the time which is necessary in order to go through with various tests.

Our present available tests include the conversational voice, the whisper, the ticking of a watch, tuning-forks of different tones, and the Galton whistle. Of these commonly employed tests, those which most nearly approach accuracy are certain tests made with the tuning-forks. These include:

(1) The determination of the relation of air-con-

duction to bone-conduction; (2) the test of the relation of bone-conduction to normal; and (3) the Weber test.

Although these tests give valuable information, there are disturbing factors. It requires so much time to wait until the tuning-fork has ceased to vibrate—only to find out that the patient did not understand what we were doing and making it necessary to repeat the procedure. In addition, all tuning-forks are of different physical characteristics; no comparison can be made from time to time unless the same examiner re-examines with the same tuning-forks; even then tuning-fork tests are subject to uncertainties which arise from one's inability to strike the tuning-fork each time with an equal blow.

Most of the tests are at best extremely crude and inexact. Tests made with the ticking of the watch or with the whisper or conversational voice are even more uncertain than the tuning-fork tests.

We all recognize the many limitations as outlined above. We might perhaps summarize our dissatisfaction as follows:

1. It requires a great deal of time and patience to conduct complete functional tests of hearing with the present methods. It would be highly desirable if one could attain simplicity and speed as well as accuracy. Only too frequently the busy practitioner finds himself making only a cursory examination.

2. Because of the lack of precision in these tests it is difficult to determine the effect of any treatment that we might undertake. After a removal of tonsils, or after a submucous resection of the septum, or after prolonged treatment of the eustachian tube by inflation or the bougie, we are naturally concerned to know whether the patient's hearing is impaired. We need a "yardstick" of measurement. I think that we have all felt at times that our main standard has been the temperament of disposition of the patient. If the patient is an optimist he will tell us that he is much improved. If he is a pessimist he will tell you that he is no better or worse. Even in prolonged observation of a deaf patient, unless gross changes occur, either for the better or for the worse, it is difficult to draw any exact conclusions as to the status of the hearing defect.

3. We all deplore the absence of any standard method of recording the results of the measurements made by the tuning-fork or other present tests. Custom has already standardized the vestibular tests, even though they are so very recent. By following the same technique, the physician may compare his vestibular findings with those of another examiner in another city on a different date. It is quite a contrast when we receive a letter from some other otologist regarding the tests of hearing that he has made. At times we wonder if there are not almost as many methods of recording functional tests of hearing as there are otologists.

4. Present methods do not furnish a basis for prescribing the type of artificial aid for hearing to meet the needs of any given individual.

Recent attempts have been made to overcome these serious inadequacies. This has been made possible because of the vacuum tube or Audion bulb. It has two principal uses: as an oscillator and as an amplifier.

Its use as an oscillator is the basis of the audiometer. Much work has been done in the perfecting of audiometers, particularly by the splendid work of research engineers of the Western Electric Company. With the audiometer it is possible to test the patient for representative tones throughout the entire range of audibility. These tones may then be reduced in loudness to the point of minimal audibility. This provides an exact quantitative measurement of the patient's auditory acuity, in comparison with an established normal. In addition, the results of such an examination can be charted with precision. Such charts show the quantitative defect for all tones throughout the range of hearing.

The other feature of the Audion bulb, the amplification of sounds, such as the conversational voice, has been utilized in an instrument designed by Professor Knudsen and the writer. For want of a better name we have called it the "audio-amplifier." This instrument consists of a speech amplifier, a device for quantitative tests of bone-conduction, a noise apparatus and an audiometer. The main feature of the instrument is that it makes double use of the same apparatus. There are two Audion bulbs. By turning a key in one direction, these two vacuum tubes are used as amplifiers for the conversational or whispered voice. Between the second bulb and the ear of the patient there is a volume control. By throwing the key in the opposite direction, the first bulb is then used to produce oscillatory currents. These oscillatory currents are carried through the second bulb, which serves as an amplifier, and then through the same volume control to the ear of the patient.

The amplifier makes a direct test of the sensitivity of the cochlea very quickly. It is possible to make a differential diagnosis between perceptive and obstructive lesions, and also to make an approximate quantitative measurement of the auditory acuity of each ear. This test is very simple and requires only one or two minutes for its completion. The examiner simply speaks a few words into the input of the amplifier and then adjusts the nature of the amplification until the speech sounds are best heard by the patient. He then reduces the loudness, by the volume control, until the patient can no longer understand the conversation. The degree of the hearing defect is then indicated by the dial on the volume control.

In testing for hysterical hearing disturbances or malingering, the conversational voice can be suddenly directed from one ear to the other by an electric switch.

In presenting this instrument for your consideration, Professor Knudsen and I will be very appreciative of any criticisms. Personally, I want to take this opportunity of expressing appreciation to Professor Knudsen for the many months of work that he has devoted to this subject. So far as I am personally concerned, the instrument that he has made meets practically every need that I can think of in daily routine practice. I rather expect the principal use of this instrument in my hands will be the amplifier portion—simply putting the receiver to the ears of the patient, carrying on a short conversation, and determining whether it is obstructive or perceptive deafness and the rough quantitative meas-

urement of the percentage of hearing defect in each ear. Not only is it helpful to be able to do this in a minute or two, but we find that the patient responds with more interest to conversation than to the mere production of certain tones. On the other hand, it is a great satisfaction to have, in the audiometer portion, an instrument that is capable of making very precise and exhaustive tests in selected cases.

CONSIDERATIONS FROM THE STANDPOINT OF PHYSICS

By VERN O. KNUDSEN, Ph.D.

University of California, Southern Branch, Department of Physics

Hearing Impairments—Hearing impairments are classified by otologists under two general types: conductive and perceptive.

Conductive impairments result from changes in the external and middle ears which diminish the transmission efficiency of the conductive mechanism. These impairments, in general, consist of an obstruction in the external auditory canal or a fixation of one or more of the moving parts in the middle ear.

From the standpoint of physics, it is a simple problem to pre-determine what the physical characteristics of these obstructions or fixations will be. An obstruction in the external auditory canal closes the "door" to the middle and internal ears. Experience, supported by physical measurements, demonstrates that shutting the door to the music room will diminish, nearly equally, tones of all pitch which enter an adjacent room. One would predict, therefore, that such obstructive deafness should be characterized physically by a uniform diminution of the hearing acuity for tones of low, medium or high pitch. Precise audiometric measurements confirm this prediction.

The physical characteristics of fixation impairments are not so simply explained as those for obstructive impairments. In order to appreciate the physical characteristics of an impairment of fixation it will be necessary to keep in mind two factors: First, tones of low pitch must possess much more sound energy than tones of high pitch to elicit sensations of equal loudness. Thus, a tone of 64 double vibrations per second must possess 10,000 times as much energy as a tone of 1024 double vibrations per second if the two are to produce equal loudness sensations in a normal ear. Second, tones of low pitch must have much greater amplitudes of vibration than tones of high pitch if the two are to possess equal amounts of sound energy. Thus, a tone of 64 double vibrations per second must have an amplitude 256 times as great as a tone of 1024 double vibrations per second for the two tones to possess equal amounts of sound energy. Both of these factors conspire to require gross movements of the conductive mechanism of the middle ear for tones of low pitch and only infinitesimal movements for tones of high pitch. Thus, if the two tones considered above are to produce equal loudness sensations, the 64 d. v. tone will require displacements of the stapes 25,600 times greater than those for the 1024 d. v. tone. One would predict, therefore, that fixation deafness should be characterized phy-

sically by a great diminution of the hearing acuity for tones of low pitch, and by only a very slight diminution for the tones of high pitch. Precise audiometric measurements also confirm this prediction.

Perceptive impairments of the most common type result from changes within the cochlea or eighth nerve. On the basis of any resonance theory of audition (and it seems to the writer that a resonance theory is the only tenable one) those portions of the tectorial or bassilar membranes which respond to tones of high pitch will be the most delicate parts of the vibrating structure, and will also be subject to greater tension than those portions which respond to tones of low pitch. It is reasonable to expect, therefore, that pathologic changes within the cochlea should produce greater destruction among the delicate and tightly stretched portions of the vibrating structure than among the relatively gross and slightly stretched portions. Hence, one would predict that perceptive deafness of the type here described should be characterized physically by a great diminution of the hearing acuity for tones of high pitch and by a lesser diminution for the tones of low pitch. This prediction is also confirmed by precise audiometric measurements.

From the above physical considerations there are three outstanding types of deafness, each of which possesses definite and distinct physical characteristics. To summarize, obstructive deafness is characterized by a diminution of the hearing acuity for tones of all pitch, fixation deafness is characterized by a great diminution for tones of low pitch and only a slight diminution for tones of high pitch, and perceptive deafness is characterized by a very great diminution for tones of high pitch and a lesser diminution for tones of low pitch.

Conductive impairments produce partial deafness because insufficient sound energy reaches the cochlea. Perceptive impairments produce partial or total deafness because the sensitiveness of the receptive apparatus within the cochlea has been dulled. Appropriate amplification of speech or music will restore hearing for those who have conductive impairments, whereas the amplification of speech or music will in general only overwork the already weakened receptive apparatus of the cochlea for those who have advanced perceptive impairments. For those who have only a slight perceptive impairment, it is probable that appropriate amplification may improve normal hearing.

The above considerations constitute the basis upon which the amplifier portion of the audio-amplifier is designed. The amplifier is designed to give (1) uniform amplification of all the frequency components of the conversational voice, (2) great amplification of the low frequency components of the conversational voice with only slight amplification of the high frequency components, and (3) great amplification of the high frequency components of the conversational voice with a lesser amplification of the low frequency components. These three types of amplification are the types required to correct obstructive, fixation, and, in some instances, perceptive impairments, respectively.

For convenience of notation and description, these three types of amplification will be called (1) "uni-

form amplification," meaning that tones of all pitch are amplified equally, (2) "*low pass amplification*," meaning that the tones of low pitch are given a large amplification, and as we go up the scale of pitch the amplification becomes increasingly less and less, and (3) "*high pass amplification*," meaning that the tones of high pitch are given a large amplification, and as we go down the scale of pitch the amplification becomes increasingly less and less.

These three types of amplification are attained by introducing what is known as a corrective circuit between the two stages of the vacuum-tube amplifier. This corrective circuit consists of an inductance, a capacitance, and a resistance. These are so arranged that, by throwing a key in one direction, the capacitance and resistance are connected in series across the input of the second vacuum tube. This provides a *low-pass* amplification. By throwing the key in the opposite direction, the inductance and resistance are connected in series across the input of the second vacuum tube. This provides a *high-pass* amplification. By leaving the key in the neutral position the corrective circuit is out, and in this manner *uniform* amplification is obtained.

The selective amplification we have just described, and the physical characteristics of the three types of hearing impairments described above, suggest the use of selective amplifiers for correcting hearing defects. Dr. Jones and the writer are at present working on the design of an artificial aid to hearing, the "magnaphone," which is based upon this principle of selective amplification. The audio-amplifier is used for "writing the prescription" for the magnaphone for each individual patient. The audiometer portion of the instrument is used for charting precisely the acuity of hearing for each ear. These charts then indicate the amount and nature of the amplification necessary to restore the patient's hearing to normal, provided the defect is of a correctible type. Then, by use of the amplifier portion of the audio-amplifier, the patient can be shown right at the time of examination what help he may expect from the use of such an instrument.

These developments, and the developments of our co-workers in this field, give a hope, therefore, of placing the prescribing of artificial aids to hearing upon the same scientific basis as the grinding of lenses for the correction of defects of vision.

1920 Wilshire Boulevard.

DISCUSSION

FRANK ALBERT BURTON, M. D. (Watts Building, San Diego)—For several years there has been a felt need for standardization in functional ear-testing. Every aurist who has done conscientious work has been impressed with the crying need for improvement in this connection. Several times during recent years the matter has been under discussion at meetings of the American Academy of O. O. and L., the Triological Society and other leading organizations.

Any effort at improvement in functional ear-testing has among its main objectives that of precision, speed, simplicity and a uniformity of technique. The Audio-Amplifier seems to adapt itself to the felt need without excessive expense when the use of the instrument is taken into account.

W. E. WADDELL, M. D. (Pacific Mutual Building, Los Angeles)—Our deepest interest and sympathy, and justly so, goes out toward the totally deaf child, yet today this child is educated by sign and oral methods that he may acquire knowledge and impart his ideas to others; also,

that he may care for himself as well as those dependent upon him; thus, so educated, he grows up without a definite knowledge of the lost sense and leads a comparatively happy and contented life.

We have about us the great army of men and women who have received an education and are following a vocation that requires the sense of hearing, who, finding their hearing impaired (this condition growing worse from month to month, unfitting them for business and social life), demand from us, as physicians, interest and help. This class of patients have gone from one physician to another. The examination is made by forks, whistle, etc., the treatments are given and if the patient is an optimist he says he is better and he may be, yet he is in a state of doubt when the next examination is made as to the result, on account of the apparent uncertainty of the many tests he has gone through in the hands of different physicians, all giving different results. Thus a standardized instrument of precision in functional ear-testing will be a great step forward in giving to these people the much sought for relief.

After advice has been acted upon in regard to diet and care of the body, after focal infections are cleared up and local treatments indicated are carried out, then, if upon the second test with this instrument of precision, the patient finds that he has improved 10, 20 or more per cent, he then has courage, something hard to impart to these patients; he also *knows* that he hears better. If he goes to another reputable aurist to check up, he finds the same result.

If after following the advice and treatment, the Audio-Amplifier shows no improvement, then, as Professor Knudsen says in his paper, "By the help of the Audio-Amplifier, we write the prescription for a Magnaphone that will fit the patient."

Functional ear-testing must be standardized, if we, as physicians, expect to give those partially deaf the relief and comfort that the teachers are giving to those totally deaf. The Audio-Amplifier, I believe, will meet this demand.

ANNA B. LEFLER, M. D. (605 Story Building, Los Angeles)—The preface to Doctor Jones' book on "Vertigo" states: "The studies in this book were originally undertaken at the suggestion of Doctor Weisenburg." This early disposition of Doctor Jones to collaborate in associated lines of work has resulted in much of practical value. He and Professor Knudsen are modest in their statements regarding the Audio-Amplifier; but great ease and satisfaction are gained by its use in testing. To be able to answer in conversational tones the questions of a deaf patient is a marked relief in a busy day. Of much more importance is the chance for standardized records with the increased interest this will afford the problems of deafness. Malignancy may cost more in physical pain and life than deafness, but the latter takes the greater toll in social and economic values.

H. G. MERRILL (35 East Second South Street, Provo, Utah)—The value of the Audio-Amplifier in otologic diagnosis and study, even so soon after its initial appearance, is well established with those of us who are using it. Our experience has made us feel that Doctor Jones is conservative when he writes, "it meets practically every need that I can think of in daily routine practice." We believe that better and more progressive ear diagnosis will date its beginning from the advent of the Audio-Amplifier.

The use of this instrument, however, is daily bringing us to a realization of our failings in diagnostic otology. Among other imperfections attaching themselves to this science is our classification of hearing defects. Doctor Jones and Professor Knudsen, in their very estimable work, have designated all cases as falling under the heads: Obstruction, fixation or perception. Personally, we strongly feel that, to reach more nearly the truth, we should retain at the head of the list the old term, "conduction." This, because we believe that the great majority of chronic progressive deafness cases does not fall under obstruction—(as here applied) or fixation—(from the standpoint of fibrosis). To explain our reasons for such a conclusion requires more time than is here permissible, and will furnish subject matter for a preliminary report we hope to offer in the near future.

In learning to use the Audio-Amplifier, we were con-

fused by the term "pass" in speaking of high and low selective amplifications. If others are having similar difficulty from this usage, might it not be better at the start to accustom ourselves to the terms of "high selective amplification" and "low selective amplification"? Perhaps such a change is unimportant, but we feel that it would have helped us in the beginning. Accuracy of diagnosis is greatly promoted by graphically charting each audiometric study.

INTRACRANIAL HYPERTENSION AND SEROUS MENINGITIS

By EDWARD W. TWITCHELL, M. D., *San Francisco*

Serous meningitis is in its simplest form a very common thing.

Puncture should be far more often done than it is.

The procedure itself is so trivial that if there is any chance of help it should be used.

A means of differentiating between meningitis circumscripta and a new growth has not been found.

DISCUSSION by Howard W. Fleming, *San Francisco*; C. E. Locke, Jr., *Cleveland, Ohio*; I. Leon Meyers, *Los Angeles*.

AFTER the specific causes of the various types of meningitis became known, there was reluctance on the part of physicians to admit or recognize a meningitis which might consist in an increase of fluid and intracranial tension, without the presence and growth of organisms. The term "meningitis" was felt to connote bacterial growth, pleocytosis, marked inflammation, and, except in the case of epidemic meningitis, a uniformly fatal prognosis. Meningism was, to be sure, rather a popular term, but vaguely meant a meningeal irritation by blood-borne toxins, a passing manifestation with no demonstrable pathology. For years cases of meningeal irritation were reported—some of them making surprising recoveries, others ending fatally, with relatively minor meningeal findings at autopsies. Some such as Austin Flint's case were, of course, tuberculous in nature; others were hydrocephalic. Those which got well must have come in another category.

The problem did not advance toward solution until Quincke introduced lumbar puncture as a routine diagnostic procedure. He reported a number of cases with favorable outcome. Some were hydrocephalic children, in whom an intercurrent disease was responsible for the aggravation of intracranial pressure; others were syphilitic and responded to mercury and iodine, but they had outspoken signs of meningeal irritation which after a time subsided. Some of the more acute cases subsided in a few days after puncture.

The constant symptoms were headache, retraction of the neck, vomiting, defective pupillary reaction, confusion, delirium, unconsciousness at times, and occasionally edema of the optic disc. Nystagmus and staggering gait occasionally occurred. The spinal fluid sometimes showed great increase in pressure. Spinal fluid findings were usually negative. Quincke's first paper antedated the present-day serology and cytology, but in his later case reports the fluid often proved Wassermann negative, with normal cell count and globulins in many instances.

Quincke grouped his cases thus: (a) Those with acute onset with acute or chronic course. (b) Those with gradual onset with either a chronic progressive course or with acute exacerbations. Many cases he regarded as instances of exacerbations of chronic hydrocephalus. According to Quincke, the chief causes were injury, mental strain, alcohol, and fever. Infection was not regarded as necessary. In fact, said he, the causes were the same as for accumulations of fluid in the pleural or peritoneal cavities. He specifically mentioned instances of arachnitis with cyst formation, and cites the cases reported by Oppenheim and Borchardt.

Placzek and Krause, in 1907, reported the case of a patient suffering from giddiness, diplopia, vomiting, and paralysis of the right facial and left lateropulsion. Operation by Krause disclosed a cyst at the undersurface of the cerebellum. Unger, in 1909, reported a case with symptoms pointing to tumor at the cerebello-pontile angle. Here syphilis was proven and mercury and iodine used, but severe papillitis developing with diplopia and adiadochokinesis, the patient was operated upon and cured by destruction of a cyst. In 1910 Oppenheim and Borchardt reported the case of a 7-year-old girl who fell from a street-car, striking the occiput. Subsequent symptoms led to the diagnosis of brain tumor, and at operation a wine-glassful of cystic fluid was obtained from the cavity of the thickened arachnoid. Bing, in 1911, reported an instance of cyst of the cisterna magna cured by operation. Quincke, Braun and Lewandowsky and others draw attention to the fact that these cysts often form after a severe blow upon the head, as in the case of the child cited above from Borchardt. Quincke speaks of a "clear case of meningitis serosa traumatica."

Redlich, in Lewandowsky's Handbuch, speaks of the difficulty in differentiating between these cysts and neoplasms. In cases of rapidly developing meningitis serosa following ear trouble, the relief obtained by lumbar puncture, according to Redlich, is of much diagnostic value.

Finkelnburg (Lewandowsky Handbuch) finds neuritis and papillitis common. The pathological findings in fatal cases are "recht spärlich." A flattening of convolutions, injection of vessels, increased fluid with cloudiness are seen, and often many bacteria. This last statement makes one wonder how such cases are kept in the class of the ordinary meningitis.

Among the more important papers of later years are those of H. Claude in Questions Neurologique d'actualite and in L'Encephale. He reviews the subject from the time of Quincke in particular, and cites the early surgical cases of Emmerson and Frazier. The occasional cystic formation, as a result of arachnoid adhesions in other parts of the brain than the base, are described, and one case of marked depression of the convexity is pictured. Mention is made of other cases reported by Muskens, Ströbe, and Uréchia. He insists upon the damage done to the hypophysis by increased intracranial pressure, and cites instances where it has been almost destroyed. From that result what he called the "syndromes endocriniens secondaires."

Claude is a vigorous advocate of the routine use of the manometer for determining the degree of pressure of the spinal fluid. He makes the usual statement that rapidity of flow at the time of puncture is no index as to the pressure, or rather that, with very high pressure, the fluid may come slowly, drop by drop. This is true only if there is some impediment to the flow. Given needles of constant caliber and a limpid fluid, the rate of flow is directly as the pressure. If the needle be stopped partially, or the fluid thick, the flow will be slowed, regardless of the pressure behind it. This much, however, is always true: a spurt of fluid means very high pressure. The Queckenstedt manoeuvre of compression of the jugulars during withdrawal of fluid will give some idea as to whether or not there is any impediment to the flow.

Claude insists that lumbar puncture be done always where there is persistent headache, vertigo, and vomiting. This should be modified by the statement; provided that one can be sure that there is no danger of the pressure from above pressing the medulla down into the foramen magnum. If a very fine needle is used and but a small amount of fluid withdrawn, this danger is much lessened. It is true, however, that lumbar puncture should be done far oftener than is now customary. Many a severe headache in the course of active infectious disease would be relieved by lowering the pressure and leaving an opening in the dura through which drainage could keep up for a day or two.

Claude holds that circumscribed cortical serous meningitis is indicated by general symptoms of hypertension with low manometric reading, focal epilepsies, myoclonus, and absence of papillitis. He mentions one case of cyst beneath the cerebellum diagnosed as such before operation. One of the points of differentiation from a neoplasm was absence of edema of the disc. As one of my own cases will show, this is by no means a criterion.

Within the past year a number of cases have come to my notice, in which the outstanding symptoms pointed to intracranial hypertension, and I have chosen four of them as representing some of the types emphasized by Quincke and Claude. Three of the four are at present in good health, although one was subjected to a formidable operation. The one who died, died, we believe, from causes not connected with the meningeal condition.

CASE I—A. F., aet. 29, nat. California. Entered St. Francis Hospital 2-24-1923. For one month he has been complaining of severe frontal headache, chiefly over either eye. An x-ray examination showed evidence of slight sinusitis. Temperature was 101.5 degrees, pulse 60, respiration 17. At the time of entrance, the headache had become very severe and there was mental confusion and persistent vomiting. There were rigidity of neck and other signs of meningeal irritation. Urine was normal and so was the blood, aside from a leucocytosis of 10,500. Fundi were normal. A lumbar puncture brought a clear fluid under increased pressure, with normal cell count and globulins and negative Wassermann. Soon after puncture, the headache, vomiting, and other signs of meningeal irritation lessened. In three days the patient was in a normal condition and has remained so since. This is a good example of Quincke's Class "A"; acute onset and acute course with rapid relief after puncture.

CASE II—J. McK., aet. 20, nat. California. Entered St. Francis Hospital 8-23-23. There had been complaint of shortness of breath for months, of occipital headache for eleven days, and of vomiting for the last day or two.

This patient was exhausted by far advanced mitral stenosis, and when meningeal signs showed themselves, a tuberculous meningitis was suspected. The patient was delirious, with retracted head and positive Kernig. The spinal fluid, which was under increased pressure, was Wassermann negative. There were no organisms, no increase of cells, and no web on standing. Under daily spinal drainage, the signs of meningeal irritation disappeared and the patient regained consciousness. Suddenly he died, supposedly as a result of the heart lesion. Blood and spinal fluid cultures had shown no growth. The relief from spinal drainage was very striking in this case and we at one time were hopeful for recovery, though aware that it could be but temporary on account of the advanced decompensation. Unfortunately, an autopsy could not be obtained.

CASE III—A. G., aet. 11, nat. San Francisco. Entered isolation ward of San Francisco Hospital moaning, unconscious, head extended, pupils dilated, and extremities rigid. He had been struck on the back of the head in a fight ten days before entry. Twenty-four hours before entry he became feverish and was found unconscious on the floor of his bedroom. He vomited several times. The nose was bloody. Brudzinski and Kernig positive. Babinski group of reflexes all positive. Leucocytosis of 29,000. On puncture, the spinal fluid squirted at least a foot. There were 18 lymphocytes per cubic mm. and increased globulins. No organisms were seen in the smear, and no growth in culture at first. Later, staph. albus was reported with a question of contamination. Nasal smear was negative. A subsequent spinal puncture showed normal cell count. The fever subsided rapidly. At the end of a week the patient was discharged in apparently normal condition. It has been learned that the patient had a mild recurrence several weeks after going home, but at present writing is well.

In this case the blow on the head probably played a large part. It was what Quincke would have called "a clear case of meningitis serosa traumatica."

CASE IV—Mrs. W., aet. 36, nat. Austria. Married at 16 and infected by her husband, who has since died. She had as treatment only some medicine which he purchased at a drug store. She began to have "peculiar headaches" in 1912. These headaches sometimes ended in unconsciousness. She remembers once calling, "Come quick, help," and then becoming unconscious. In 1920 she came to San Francisco and at that time suffered greatly with thirst and polyuria. This undoubtedly was due to the hypophyseal compression, of which Claude speaks. By September, 1920, she was so blind that she had to be led around. Then she was given vigorous anti-syphilitic treatment and recovered her sight. She never menstruated after 1920, another associated endocrine symptom. In May, 1923, things grew worse again and the headaches were so severe that she yelled, as she expressed it. She had a spell of projectile vomiting and her eyes crossed. She talked indistinctly and grew irrational. Finally the left arm and the fingers of the left hand grew numb. She entered St. Francis Hospital 6-30-23 stuporous. The pupils were equal with poor reaction to light. The left abducens was weak. The discs were blurred and swollen, and there were hemorrhages and exudate in the retinae. There were left-sided asthenia, adiadokokinesis and dysmetria. A diagnosis of tumor in the left posterior fossa was made. Operation was done by Dr. Howard W. Fleming on July 1. A cyst was found occupying the space of the cisterna magna, walled by an arachnoid that was thickened like chamois skin. She left the hospital, ambulant, on July 24, but soon had a return of some symptoms, especially an uncontrollable vomiting. The discs, which had receded, swelled again and she was taken to the University of California Hospital. Here she was given intravenous injections of sodium iodide. Gradually she grew better. Her weight increased from 91 to 145 pounds, and her strength grew progressively greater. The nerve heads now are flat, vision is good, and the cerebellar signs are almost vanished. There was for some time a great deal of occipital soreness, but that has for the most part disappeared. It may be noted here that several blood Wassermans in recent years were negative. I have omitted all discussion of surgical details, with the idea that that side of the case will be subsequently treated by Dr. Fleming, upon whom the whole burden of the operation fell.

The first of these cases is one of acute hypertension of unknown origin. It is the type we see oftenest, and many such are recorded by Quincke, Claude and others. The symptoms of headache, retraction, vomiting, and mental confusion were pronounced. For unknown reasons there was a sudden rise of tension which produced them. Shortly after withdrawal of what appeared normal fluid, all symptoms subsided and the patient was rapidly restored to normal. The original cause probably being a transitory one, puncture was of undoubted value and was the only thing needed. The second case was a far more serious one. Some of the factors are still in doubt. No guinea pig injection was made and tuberculosis is a possibility, but the usual pleocytosis, increase of globulins, and web were wanting. The amelioration after repeated puncture was so marked that it was felt that the boy had a chance of recovery from the meningeal complex. The third case would come under Quincke's heading of meningitis serosa traumatica, but the leucocytosis of 29,000 is unexplained. The bloody nose made one think of extension of trouble from the sinuses, although nasal smears were negative. In any event, the puncture was a great help. The relapse after leaving the hospital was in keeping with the experiences of others. In such cases, cyst formation may result later.

The fourth case was one of meningitis serosa circumscripta syphilitica. Here a lumbar puncture might have been fatal, while cistern puncture might have given temporary relief. The only hope for the moribund woman was immediate operation, and fortunately it led to the finding and evacuation of a cyst. The reason for subsequent flare-up was never understood.

To sum up: Serous meningitis is, in its simplest form, a very common thing. It is one of the conditions in many cases of acute illness, and the distress which it causes can be relieved by prompt puncture. Puncture should be far more often done than it is. Whenever a headache is very persistent, and the usual remedies fail to relieve, puncture should be thought of. The procedure itself is so trivial that if there is any chance of help it should be used.

A means of differentiating between meningitis circumscripta and a new growth has not been found, but the fact that these cysts are rather frequent should keep one on the alert, for the operative treatment of them forms a very bright spot in what is a pretty dark corner of surgery.

909 Hyde Street.

DISCUSSION

HOWARD W. FLEMING, M. D. (380 Post Street, San Francisco)—Dr. Twitchell has asked me to discuss the surgical features of the patient operated on. At the time the patient was first seen she appeared to be in extremis. Examination was difficult, due to the lack of co-operation. She was unconscious, there was moderate cervical rigidity. The fundi revealed bi-lateral choking of several diopters. The extra ocular muscles were uninvolved, and a facial paresis was apparent.

The history of findings, made prior to loss of consciousness, made a cerebellar involvement beyond question. Our pre-operative diagnosis was cerebellar tumor.

An emergency operation was done that day under ether anesthesia, with the patient in the prone position. The usual cross-bow incision was made and the occipital bone

removed, including the posterior margin of the foramen magnum. Before opening the dura, it was necessary to puncture the lateral ventricle to reduce the intra-cranial pressure. The dura was opened widely, revealing a large cystic tumor, which was a part of, or overlying, the posterior cistern. The walls of the cyst were clear and appeared to be markedly thickened arachnoid tissue. It was necessary to cut the wall with a scissors before it could be opened widely. An abnormally large amount of fluid escaped. The greater part of the cyst was opened up and some excised for pathological examination. There was a marked herniation through the foramen magnum, and it was necessary to remove the lamina of the atlas and axis before the cerebellar tonsils could be elevated. The patient had a very stormy post-operative course. For several days her temperature rose as high as 105 and 106, with a very rapid pulse. About the seventh day she began to improve. All the neurological signs enumerated above disappeared. The choked discs subsided rapidly.

The patient had one relapse, which Twitchell has mentioned. At present she is feeling extremely well, and her only complaint is slight unsteadiness at times and a painful sensation in the region of the operative scar. Unfortunately, the tissue excised for diagnosis was lost in the pathological department. However, there is very little doubt but that this is a case of meningitis serosa circumscripta. A search was made for a posterior fossa tumor and both lobes punctured. At the present time the patient has no herniation at the site of occipital decompression, and the discs show no evidence of choking. We feel that with effectual anti-luetic therapy her prognosis should be good.

C. E. LOCKE, JR., M. D. (Cleveland Clinic, Cleveland, Ohio)—I want to thank Dr. Twitchell for his most excellent and instructive paper. Three cases, similar in symptomatology and operative findings to Twitchell's Case IV, yet with no proof of syphilis, have come to my notice. In one of these patients, histological study of the thickened arachnoid membrane showed definite round-cell infiltration. All three of these cases did exceedingly well after operation.

The differential diagnosis of circumscribed serous meningitis and brain tumor presents a difficult problem, especially when the latter is located in the posterior fossa. In this region, as the result of interference of the circulation of the cerebrospinal fluid, the pocketed subarachnoid fluid causes internal hydrocephalus and produces the usual signs and symptoms of increased intra-cranial pressure.

In contradistinction to tumor, it has been my experience that patients with circumscribed arachnoiditis of the posterior fossa complain of pain, stiffness and tenderness in the suboccipital region, diplopia and transient numbness of the extremities, and that the usual intra-cerebellar signs are less pronounced. With circumscribed arachnoiditis, the angle cranial nerve signs are usually absent, I believe. In cases of circumscribed serous meningitis, a preliminary history of a general acute infection may often be found.

I. LEON MEYERS, M. D. (517 Rillstreet Building, Los Angeles)—Serous meningitis as the cause of intra-cranial hypertension and its resulting manifestations is met with not only in conditions with general neurologic disturbances, but also in those with focal phenomena. It should, consequently, be considered as a possible cause of the trouble in any obscure case of intra-cranial hypertension.

Among the cases reported by Twitchell was one which followed a head injury. This coincides with the convictions which I have ascertained for some time that traumatic epilepsy, in the absence of focal irritation, is brought about by serous meningitis, the spinal fluid in these cases being practically always under increased tension. This is undoubtedly true of also the other so-called post-concussional syndromes, as, for example, the amnesic, the aphasic, and the labyrinthine, conditions which are also associated with increased fluid pressure, and not infrequently with the presence of globulin and a slight pleocytosis.

Particularly interesting, however, are the cases of serous meningitis with phenomena of focal brain irritation, such as Jacksonian spasms, cranial nerve palsies, nystagmus, and cerebellar signs. These cases are generally referred to as pseudo-tumors and have been noted even in the absence of such focal pathology as was found

in Dr. Twitchell's Case IV. Mohamed Saleh (1912) collected thirty-two such cases from the literature, in thirteen of which necropsy revealed pathology of only a minimal character.

A case of this type came under my observation at the Los Angeles General Hospital in 1922. The patient, a man 48 years of age, has bilateral ptosis of the upper eyelid, and marked limitation of all extra ocular movements, especially those which require the action of the right oculo-motorius. He had a horizontal nystagmus to the right, and was markedly ataxic. His gait was cerebellar in type, and he tended to fall forward and to the right. The subjective symptoms were: Severe headaches, diplopia on looking to the left, and dizziness. He was extremely apathetic. While at the hospital he had numerous attacks of unconsciousness, with convulsions. The convulsions were in the nature of tetanus-like seizures, and suggested a tumor of the vermis. There was no history of trauma. The Wassermann on his blood was negative, and the spinal fluid which was examined several times was, except for an increase in the tension, entirely negative. The patient remained in this stuporous condition for about ten days, and then began to improve. The improvement continued steadily, and within a week all symptoms and signs had disappeared so that he was able to go home. Professor Barany visited Los Angeles a few months later, and at my request examined this patient, but nothing abnormal was found, the patient stating at the same time that he felt perfectly well ever since he left the hospital. The marked improvement, and finally the complete disappearance in this patient of all signs and symptoms, which followed so closely, the lumbar punctures, and the absence of spinal fluid findings which are associated with epidemic (lethargic) encephalitis, leads one to believe that this was a case of serous meningitis of the type known as pseudo-tumor cerebri.

STRICTURE OF THE URETER AND DYSMENORRHOEA

By RAYMOND L. SCHULZ, M. D., *Los Angeles*

The chief reasons for this paper are to explain how stricture of the ureter develops, why it causes symptoms; how it may cause dysmenorrhoea; to emphasize some of the unusual features of the subject and to urge the importance of careful diagnostic treatment of these patients.

Stricture of the ureter should always be thought of in all cases of vague lower abdominal pain in either side; likewise severe menstrual pains.

Stricture of the ureter is perhaps the commonest urological condition that we have to deal with in women.

DISCUSSION by Norman H. Williams, *Los Angeles*; Clarence W. Page, *Berkeley*; E. J. Eytinge, *Redlands*; R. H. Van Denburg, *Los Angeles*; Harry H. Wilson, *Los Angeles*.

NOTWITHSTANDING the numerous articles on stricture on the female ureter, there are enough of these patients who go unrecognized for varying lengths of time, so that the subject is still of timely interest. Stricture of the ureter is perhaps the commonest urological condition that we have to deal with in women.

Many of the patients have had all sorts of examinations, without locating their trouble. The ordinary methods of cystoscopy, ureteral catheterization, and pyelography may not reveal any abnormality, but by the proper method we can determine quite accurately if the symptoms originate in the urinary tract or not, and, if they do, we can reproduce exactly the pain from which these patients

have been suffering so as to leave little doubt about a diagnosis.

Many of these patients have undergone operative procedures on the abdomen, such as removal of the appendix, gall-bladder exploration, removal of ovaries, tubes and uterus, without obtaining relief, when the underlying condition is stricture of the ureter. It is this lack of thorough diagnosis which tends to bring surgery into disrepute with some people. Too much emphasis cannot be placed upon the importance of considering the possibility of ureteral stricture in every case where there are vague abdominal pains, though at the same time we must not expect that this condition will explain every one of these puzzling cases. The tests for ureteral stricture should be used with discretion, depending upon history and physical findings.

A clearer understanding of the underlying pathological condition, its relation to focal infection and to physiological disturbances, should help in the earlier recognition of these cases.

Any condition that produces a chronic lymphadenitis of the pelvic lymph nodes, potentially, can be a causative factor in producing an ureteral stricture. Common causes are chronic tonsillitis, infections of the teeth, both of which are known to cause poisoning of remote parts of the body at times. Also chronic cervicitis following lacerations of the womb, infections of the tubes and ovaries by direct extension to the pelvic lymph nodes. If these conditions are treated, the inflammation of the lymphatics subsides, and sometimes the symptoms of pain from the ureteral obstruction quiet down. Many patients with pains from ureteral stricture give a history either of repeated attacks of tonsillitis or of having had considerable dental work, such as root fillings. In the absence of such a history, the mere inspection of the tonsils has revealed enlargement, and in one patient there was a chronic abscess about ready to break, though throat trouble was denied.

The usual location of simple strictures is in the broad ligament portion of the ureter, and also in that portion along the pelvic wall at the bifurcation of the internal iliac vessels. In both regions there are numerous lymph nodes in intimate contact with the ureter. Hunner reports that these have been found enlarged at operation, and that the stricture formation in the ureter varied from a slight annular degree to diffuse cartilage-like thickening, for several centimeters, of its length and to a thickness of 1 cm. The infiltration may be confined to the ureteral wall, or there may be much periureteritis.

Why should the pelvic lymph nodes of all the groups in the body be practically the only ones to cause trouble as a result of focal infection? How can the remote production of the ureteral stricture, as a result of repeated tonsillitis or other focal infection, be explained? First of all, these pelvic nodes are located next to a vital organ where only slight tissue changes are necessary to cause a disturbance. The lymphatics in other parts of the body are less likely to cause serious trouble on neighboring tissues, as long as they do not interfere with the functions of surrounding tissues. Inasmuch as the uret-

eral lumen is naturally very small, it takes but little pathology to cause trouble. Tonsillitis is a disease of lymphatic tissue. Infection is very apt to be disseminated to other portions of the body during an attack, and lymph nodes elsewhere become involved secondarily. The infection or its toxin may spread beyond strictly lymphatic tissue and involve neighboring structures. When such perilymphadenitis extends to an easily vulnerable organ like the ureter in the iliac and cervical gland regions, inflammatory changes are produced in the wall of the ureter. When these lymph nodes become inflamed repeatedly, there is a cumulative effect by the formation of fibrous scar tissue or fibrosis in the wall of the ureter. With the contraction of this scar tissue, symptoms of ureteral obstruction follow. It is probable that all or most of the pelvic lymph nodes take part in the inflammatory process secondarily to a focus of infection elsewhere, but only the lymph nodes in the cervical and iliac gland regions are heard from because they lie in contact with the ureter and, through it, cause trouble.

At first, there is a periureteritis, and as the infection extends, the ureter itself becomes involved in all its coats. Inasmuch as the ureter is naturally a relatively small tube, only slight narrowing is necessary to produce symptoms.

The urine is carried through the ureter by peristaltic waves similar to the intestinal waves. When obstruction of the ureter occurs, its first effect is an increased tension above the site of obstruction, the same as in intestinal or any other obstruction. If the obstruction is partial, nature compensates, to some degree, in trying to overcome the obstruction by hyperactivity of the musculature above. When obstruction of the bladder occurs gradually, hypertrophy of its musculature follows; similarly, hypertrophy of the heart occurs back of the point of obstruction. Likewise, in intestinal obstruction, hyperactive peristaltic waves are sometimes seen above the point of obstruction.

Undoubtedly, a similar process takes place in the ureter. The first effort on the part of nature to overcome the ureteral distension is an hyperactivity of the musculature above the point of obstruction. If the muscular activity of the ureter and its subsequent hypertrophy are sufficient to expel its contents into the bladder, there is not apt to be much dilatation of the ureter. At this stage there are apt to be cramp-like, colicky pains in the abdomen from the partial obstruction and hyperactivity of the ureter. As soon as the obstruction increases so that its resistance is greater than the peristaltic effort of the ureter, then dilatation occurs. As a rule, it begins just at or above the obstruction and extends upwards gradually as the contracting power of the musculature is overcome. If the process continues, hydroureter and hydronephrosis result. Dilatation of the ureter and hydronephrosis are the result of obstruction. The absence of dilatation in an ureterogram, however, does not prove the absence of stricture of the ureter.

Intermittent pain of varying degrees of intensity is the most common symptom. It is often suggestive of the colic similar to the passing of an ureteral calculus. Often it is in the appendix region or slightly lower on either side. Sometimes it is de-

scribed as radiating around toward the back. Sometimes it is deep-seated in the pelvis or ovarian regions and penetrating through toward the back.

Pains like Dietl's crisis should always be investigated for stricture of the ureter. In one instance, such attacks of the most excruciating pain occurred at times when the patient unconsciously took a very deep breath. She felt the most severe shooting pain in the left loin and back that lasted only an instant, but was of such severity as almost to produce collapse. The probability is that a moderate amount of urine had been collecting in the renal pelvis, its flow to the bladder was partially obstructed, the deep inspiration and contraction of the diaphragm produced sudden additional pressure upon the kidney, compressing it upon an excess of fluid in the renal pelvis and thus giving the same symptoms, but only much more intensified as those obtained when the kidney pelvis is overdistended by injection. Many cases of movable kidney produce few or no symptoms. If there is pain, and kidney suspension has not given relief, obstruction may be present in the lower portion of the ureter, causing all the symptoms. Every ureter should be investigated for stricture before any operation for kidney suspension is done; likewise, cases of renal and ureteral calculi and hydronephrosis having pain.

It should be questioned if the pains described as Dietl's crisis are in reality due to a twisting of the renal pedicle of a movable kidney. Body tissues are not very apt to become kinked of their own accord. The flexibility is usually sufficient to allow considerable bending of a long pedicle, without obstructing the lumen of the ureter or blood vessels. It would take a pretty sharp kink to really cause sufficient compression of any of these tubes to produce pain symptoms, particularly such as are liable to last for a couple of days. A sudden stoppage of arteries elsewhere by compression does not cause such sudden pain, why should compression of the renal vessels cause such excruciating pain, and so suddenly? The sudden compression of a kidney that is distended to capacity on account of a ureteral stricture is a much more logical explanation for the cause of Dietl's crisis.

Urinary symptoms, such as bladder pain, frequency, burning, dysuria, and ureteral pain, are quite common, especially when there is infection. The infection and urinary symptoms may be intermittent. In such cases where there is infection, fever may occasionally occur, particularly following ordinary ureteral catheterization. Such a fever may last many days and the patient may be very sick.

In discussing the symptoms of ureteral stricture, it is particularly desired to call attention to the importance of some cases of dysmenorrhoea that are caused by ureteral stricture. Dysmenorrhoeas that have not been relieved by the ordinary methods should certainly be tested for ureteral stricture. The test is of lesser severity than other surgical procedures, and should be applied first.

How can menstruation affect stricture of the ureter and cause the so-called dysmenorrhoea? We know that congestion of any tissue produces a swelling of that tissue by stasis in the blood vessels, and subsequent edema. At the beginning of menstruation, or a few hours previous, the cramp-like pains

begin, and often after its onset the pain lessens; in other words, the congestion of the pelvic vessels is partly relieved. Under normal conditions, a stricture of the ureter may be just large enough to permit urine to pass through without any hindrance. Produce a swelling of the pelvic tissues around and in an ureteral stricture, and there may be just enough additional constriction to cause obstruction and with it the hyperistalsis or cramps in the ureter. The easiest explanation in the past has been that the pain of dysmenorrhoea is a cramp of the uterus. The recumbent position partially relieves the pelvic congestion and, indirectly, the ureteral obstruction, consequently the pain is less severe.

On examining the abdomen, fairly deep palpation is usually permissible, even over the tender portions. Tenderness is more apt to be found at the lateral margin of the rectus and slightly lower than McBurney's point. Ofttimes the abdominal findings are remarkably negative.

Urinary infection and pus are not difficult to determine. A catheterized specimen should always be obtained for examination. Very often, where ureteral stricture is present and causing chiefly symptoms of pain, the urine may be perfectly clear. It is important to remember this, that a clear negative urine does not rule out the possibility of ureteral stricture.

With a history suggestive of ureteral stricture, are we going to do a pyelogram and bilateral ureteral catheterization the first thing, or should we proceed to relieve the patient's pain as soon as possible, even though we have to defer the completion of our tests until a later period?

First of all, we should always rule out urinary tuberculosis by careful examination of a bladder specimen. Then we proceed to determine whether to use ordinary methods of ureteral catheterization in order to differentiate the two sides, or whether special precautions are necessary so as to avoid complications.

Where pain symptoms are limited to one side, the immediate test with a wax bulb-dilating catheter is often desirable, because it gives quicker relief from pain if there is a stricture. When considerable pain is present in both sides and infection in the bladder urine, it is well to be very cautious and oft-times advisable to test only one side at a time with the wax bulb catheter, the bad side first. When the reaction has subsided, the other side is tested similarly. In this way the dangerous reactions of stricture cases and pyelitis can be controlled, and we avoid putting both kidneys temporarily out of commission simultaneously.

The alarming symptoms that may follow bilateral ureteral catheterization in cases where there has been pain and infection are familiar to most urologists. All previous symptoms may become very much more intensified. The pain may be terrific, the temperature may go to 104 and 105, there may be delirium. These symptoms may last for a considerable time or subside as soon as the edema in the stricture portion has subsided after being catheterized.

If there has been urinary trouble for a long time and the combined kidney function is impaired, temporary anuria may occur. At such times it is very important not to catheterize both ureters simultane-

ously. By bearing in mind that such dangerous symptoms may be due to ureteral obstruction, and by following immediately with dilatation or leaving a large catheter in place for drainage, these symptoms can be brought under control more readily.

Definite rules cannot be laid down. It is necessary to study each patient individually and outline the procedure accordingly. One must be familiar with the untoward reactions liable to follow any of the various procedures and be prepared to meet them as they occur, or, better, use such methods from the very start which tend to avoid trouble, even though we cannot always get all the information at the first examination we would like. In many cases we can give the patient quicker relief if we proceed intelligently. Accurate diagnosis is of first importance. It is accomplished best by means of the wax bulb catheter and the characteristic pull of the stricture when it is withdrawn. A plain catheter will pass through a stricture without dilating it and can produce just enough local trauma in the stricture itself to cause its closure by the resulting edema. In the presence of infection this is all the more serious, because it subjects the kidney parenchyma to the infection and usually causes high fever. As stated above, this will sometimes subside spontaneously, but usually requires dilatation or a prolonged convalescence. Partial dilatations are not effective enough in giving permanent relief. Unless the stricture has been overdilated, it is apt to recur. A severe cold or attack of grip is apt to bring about a recurrence when a stricture has not been dilated sufficiently. As to the size to which dilatation should be carried, no hard and fast rule can be made. Overdilatation is necessary.

The passing of a wax bulb catheter for diagnosis accomplishes the beginning of dilatation. If we use larger wax bulbs subsequently, there is apt to be so much pulling on the ureter when the catheter is removed, that it is exceedingly painful. To avoid this, special dilating catheters and bougies are used. Inasmuch as there is no shoulder at any portion, they are readily withdrawn through a stricture with but very little traction on the tissues, and almost no pain.

Patients in whom strictures are dilated insufficiently and soon after develop recurrences are apt to become discouraged. They begin to drift from one to another, each time becoming more skeptical and difficult to work with on account of their contrary attitude. If dilatation is to be attempted, it should be done right and not played with. Dilatation with the Garceau catheter and Brown Buerger cystoscope is not enough to cure these cases, those thus treated are apt to recur.

In all medical and surgical treatment it is always important to remove the original cause of the trouble. Only such tonsils as definitely show disease should be removed at the same time that dilatations of the ureter are begun. Otherwise, tonsillec-tomy is not always necessary, but should be considered when there are recurrences or when dilatation does not seem to give the expected relief, provided that there are no other foci of infection. If dilatation with a Garceau catheter fails to relieve symptoms, that would not be an indication for tonsillec-tomy. Garceau catheter dilatation is inadequate, in

the first place. By gradually dilating a stricture, we soon learn whether results are to be obtained by this method alone, or if trouble elsewhere is to be looked for.

STRICTURE OF THE URETER SHOULD ALWAYS BE THOUGHT OF IN ALL CASES OF VAGUE LOWER ABDOMINAL PAIN IN EITHER SIDE; LIKEWISE SEVERE MENSTRUAL PAINS

There may or may not be urinary symptoms. Pyelitis is very apt to be accompanied by stricture, and whenever infection is present in the urine it is well to be cautious. The urologist should be on his guard to consider the possibility of stricture when pain following ordinary ureteral catheterization becomes unduly severe, and should not hesitate to investigate and dilate a stricture so as to give immediate relief. Urine and x-ray findings may be entirely negative. Overdilatation is necessary to cure a stricture.

1020 Story Building.

DISCUSSION

NORMAN H. WILLIAMS, M. D. (1052 West Sixth Street, Los Angeles)—Doctor Schulz has, I believe, approached what will probably prove to be a source of relief from certain types of pelvic pain. The patients who will probably get most relief by dilatation of the ureter may perhaps be divided into three classes. First, those of the dysmenorrhea occurring in nulliparae. Second, pelvic pain resulting from marked retro-version. Third, those patients in whom there is chronic laceration of the cervix with subsequent chronic infection producing pain in the pelvis.

The dysmenorrhoea in the first class may readily be caused by the marked congestion which characterizes the early phases of menstruation. The tissues are necessarily swollen, thus compressing the ureter in its broad ligament portion sufficiently to cause an increased peristalsis of the ureter. One finds, of course, occasionally in this type of case sufficient obstruction of the cervical canal to account for pain. However, there are many cases in which from an anatomic viewpoint this type of obstruction cannot be the sole cause for pain and it is in these that compression of the ureter is many times the disturbing cause. Following the onset of the menstrual flow and the subsequent subsidence of the pelvic congestion the pain disappears.

In the second group where marked retro-version is present there is often pelvic pain on either side, or both, which is caused by torsion of the ureter which doubtless causes more or less mechanical constriction. When the uterus, in these cases, is held up by pessary or by suspension this torsion is relieved and the pain subsides.

In the third class are patients in which the chronic infection of the cervix is present as the result of chronic laceration. As Schulz has mentioned in his paper, the constriction of the ureter is caused by enlargement of the lymph nodes immediately in the vicinity of the ureter in its pelvic portion. These are the patients who are frequently operated upon for appendicitis as no other definite pathology is found upon examination. It is, therefore, incumbent upon the surgeon to definitely ascertain if any ureteral disturbance is present before concluding that a possible chronic appendicitis is the sole cause for pain. Many times this pain will completely disappear following a repair of the cervix.

CLARENCE W. PAGE, M. D. (Physician's Building, Berkeley)—The diagnosis of ureteral stricture, not due to stone, was seldom considered until the work of Hunner demonstrated the frequency of this condition as a cause of many obscure gynecologic symptoms. Appreciation of its importance is still far from general recognition, and this paper by Schulz is, therefore, timely.

While the technic of the examination is comparatively simple, considerable skill and experience is required to

detect some of the milder cases. The results that have been achieved by the correction of this lesion, however, are now sufficiently established to justify the opinion that such an examination should be more commonly carried out in the types of patients Doctor Schulz so well describes.

E. J. EYTINGE, M. D. (118 Cajon street, Redlands)—Doctor Schulz's paper adds to the growing importance of stricture of the ureter. Some of his points of technic are to be especially emphasized.

1. The avoidance of over-instrumentation at one sitting.

2. The chief diagnostic point being the "hang" of the catheter. It is fortunate that the Kelley cystoscope can be used for the work considered, as it is the only instrument in which the "hang" is dependable.

3. Overlarge wax bulbs are not only painful, but the wax bulb pulls off too easily.

Removal of the primary focus as well as the continued overdilation is necessary to prevent recurrence.

R. H. VAN DENBURG, M. D. (Merchants National Bank Building, Los Angeles)—As Doctor Schulz has said, "stricture of the ureter is perhaps the commonest urological condition that we have to deal with in women." It is, without doubt, the commonest and most frequent pathological condition, and is one of the chief causes of years of suffering to many women.

It is the cause of more kidney changes than any other one factor. It accounts for hydronephrosis, pyelitis, and pyonephrosis. It is more frequent than ureteral stone and largely contributes to its cause.

Its causes are clearly explained in this paper, yet the matter of diagnosis requires patient and careful technique. The symptoms are so strikingly like ureteral calculus that this must first be ruled out. However, the multiplicity of symptoms, often with severe bladder disturbance, lead one to suspect stricture rather than stone. And again, in mild cases, only few symptoms may be present and the urine entirely negative.

The chief point in the diagnosis is in the proper kind of wax-bulb catheter used, and best through a Kelly endoscope, which is best adapted to its use. The dilatations are best accomplished by different sized bougies carefully introduced and not too many at one sitting. The Garceau catheter is insufficient, as Schulz has said.

It is both surprising and most gratifying to see the relief obtained in patients who have suffered over a long period of time, who have been on the operating table through some incorrect diagnosis.

HARRY H. WILSON, M. D. (Brockman Building, Los Angeles)—Judging from my own experience, I am inclined to believe that the large percentage of physicians, other than urologists, are unfamiliar with the frequency of stricture.

In the process of diagnosis it is so important for the welfare of the patient and the standing of the physician as an individual, as well as of the profession as a whole, that the real cause of patients' symptoms be diagnosed before they are submitted to operation or long treatment which may be useless if the true cause is undetermined.

The tendency for each man to find diseases or conditions in the field in which he specializes is so well known that we must be all the more careful to give our patients the advantage of unbiased examination if possible.

Specifically—any woman with pain in the abdomen and not clearly defined pathology directly explanatory of her pain should surely have an examination by a competent urologist before she is operated upon for some undefined female trouble.

It has been my pleasure to have seen several patients cured of severe pain from dilation of the ureter after other operative and long-continued medical treatment had failed to help them.

DOCTOR SCHULZ (closing)—When Hunner first published his work on stricture of the ureter, tremendous skepticism arose, which, no doubt, has interfered with the more general application of his teachings. Some of the leading urologists of the country were loud in their

denunciation of his claims. Hence, the writer appreciates all the more the support that has been given by those who have discussed this subject. The occasional opposition encountered nowadays seems to come from those sources where the methods of diagnosis have been improperly or unskillfully applied, or where the patients have not been selected. There should be a word of warning against the indiscriminate and unskillful application of the tests; neither should the possibility of co-existing lesions elsewhere be overlooked.

The remarks brought out in the discussion are all in accord with the subject. It is encouraging to learn that stricture of the ureter is beginning to receive more general recognition. It is hoped that the explanation of the mechanism of this condition will make the subject clearer to a greater number of physicians.

Clinical Notes and Case Reports

ROCKY MOUNTAIN SPOTTED FEVER— REPORT OF A FATAL CASE

By BEAUMONT BROWN, M. D., AND
GEORGE MAGEE, M. D.,
Yerington, Nevada

This report of Rocky Mountain spotted fever near Lake Tahoe is a matter of considerable importance to both public and personal health doctors, as well as to the people of Nevada and California.

Prompt energetic action NOW might prevent subsequent extensive expense and loss of life.—EDITOR.

This case is reported because we know of no other cases coming from this extreme western section of the state.

J. P., 44, rancher. Family history: negative. Past history: typhoid, age 18. Present illness: On May 24, while driving cattle near Como, about thirty-five miles east of Lake Tahoe, he was bitten by several ticks. He noticed no symptoms until May 28, when he had a chill followed by severe headache and pains in the joints and lumbar region. These symptoms continued until June 4.

The headache was frontal and throbbing. There was a slight unproductive cough. Constipation was present, and the urine was reduced in amount. The face was flushed, the conjunctivae injected, and the pupils reacted normally to light and accommodation. There were no adenopathies and no stiffness of the neck. Respirations were 30, the lungs were clear; pulse 100, full and strong; blood pressure 140/90, and there were no adventitious heart sounds. The abdomen was not tender; liver and spleen not palpable. The reflexes were normal. The urine showed a specific gravity of 1022, acid. Alb. 0; sugar 0, but with great numbers of granular and blood casts. The blood Hg. 80 per cent; r. b. c. 4,400,000; w. b. c. 16,000. Polys. 60 per cent; l. m. 20 per cent; s. m. 15 per cent; trans. 5 per cent. Eosin. 0. Baso. 0. Wassermann negative. Blood culture not taken. *Dermacentroxenus rickettsii* not found in smears. Tissue sent to Dr. G. Rusk for biopsy.

At this time (June 1) a faint rash could be seen, consisting of rose-colored macules about 1-3 mm. in diameter, not elevated, and disappearing on pressure. The rash was more prominent on the wrists, ankles, arms, and back. By June 4, the macules assumed a purplish color and became larger and did not disappear on pressure. On June 5, petechial hemorrhages of varying size appeared in the cutaneous and subcutaneous tissue. The skin was not sensitive except on the scrotum, where there was a hemorrhagic area the size of a dollar which was very tender. From June 1 to June 4 his condition continued practically unchanged. On June 4 he became irrational. The temperature dropped to normal, the pulse increased to 130, and the blood pressure dropped to 80/60. He gradually became worse and died June 8, the twelfth day of the disease.

ADRENALIN (INTRACARDIAC) SAVES CESAREAN INFANT

By JULIUS R. HAMILTON, M. D., Hollywood, Calif.

EDITOR'S NOTE—*Doctor Hamilton here presents the kind of a case report that delights, because his useful message is so briefly, yet withal so well presented, that it will be widely read.*

As the result of an ankylosed condition of practically all joints due to a long-standing arthritis of about seventeen years, it was necessary at termination of pregnancy to effect delivery by Cesarean section. The operation and subsequent recovery of the mother was uneventful. The placenta was attached to the posterior surface of the anterior wall of the uterus, and it was necessary to continue the incision through it, which, of course, interfered with the blood supply of the child. The cord encircled the child by several turns, and by the time this was freed and the child delivered, though with no undue delay, there were no signs of viability in the child whatever. The color was and remained grayish, no flushing, no efforts of respiration, and no heart sounds. The many usual methods of resuscitation were employed over a period of at least fifteen minutes, with negative results, after which time I resorted to an intracardiac injection of 8 minims of 1 to 1000 solution of adrenalin. Artificial respiration was continued, and in perhaps thirty to forty-five seconds I detected a slight fluttering impulse under my hand which was over the heart. This flutter was repeated, and then impulses were distinctly present, which became rapidly more regular and stronger. It was perhaps five or six minutes later, artificial respiration being constantly employed, before voluntary respiration was established. There was no further medication, and to the present time, which is four months, the child seems perfectly normal.

I felt a little hesitancy in using a dose as large as 8 minims, thinking of possible convulsions if successful in resuscitation, but the moribund state over that period of time, I thought, warranted it, and there were no ill effects whatever. I have purposely delayed reporting this case, to note any possible resulting complications due to the above procedure, but have discovered none, and of the four cases I found reported, three had died within thirty-six hours.

THE AFTER CARE OF INDUSTRIAL ACCIDENTS

By A. J. LANGAN, M. D.,
First National Bank Building, San Pedro, Calif.

It is mainly with the after care that the average industrial surgeon is mostly concerned. The after care is where most surgeons make the mistake of taking for granted that the injury is progressing satisfactorily, and allow a nurse or assistant to follow up the treatments. It is in this manner that contractures, ankylosis, infection, slipping back of fractures, are most apt to occur and result disastrously, both for the patient and for the surgeon. It is far better to have a patient report daily, if for nothing more than a casual glance, than to allow a case to progress unseen from day to day, allowing only weekly or bi-weekly visits. To be sure, daily visits mount into the expense of the care of the patient, but better cut the fee in accordance with the standard or usual fee for such work and have satisfaction than to allow patients to remain away until some complication develops, which will cost triple the extra surgical cost.

In the proper handling of cases in the after care, is the real secret of success in handling industrial accident cases. In my office the daily visit system is practiced; it inspires the confidence of the patient and allows the surgeon to forestall any possible complications. Many men have not the facilities for proper home care. To these men the daily hand or foot bath, the proper application of a loosened splint, the instillation of collyria or withdrawal of soiled drainage and re-insertion of new, means the more rapid healing and a quicker return to work. Close contact with a patient brings confidence to the patient, and confidence means better co-operation with the surgeon.

No industrial surgeon's equipment is complete without

proper facilities for carrying out a good measure of physiotherapy. The application of physiotherapy in all its various phases is not the haphazard routine that it has been in years gone by, but a special branch of after care in which every surgeon should aim to make himself proficient.

In the Alpine lamp and the Quartz lamp, we have efficient agencies for the removal of pain. In the pain of back sprain, ankle sprain and the general bruises, which are so common, we have a most useful agent if properly used. On the other hand, the Quartz lamp can do much damage if left to the hands of a novice. I have seen several severe burns as the result of too diligent operation of the Quartz light. In the ulcers resulting from injury to varicose legs, I have seen healing progress when all other measures seemed to fail. Indolent granulations, which seem to resist all other treatment, very often resolve and healthy granulations begin, as in old burns of long standing. As to the depth of penetration of the various lights, there is some doubt that it goes very much below the surface covering, but leucocytosis and blood supply are increased.

In diathermy, we have at our command a means of introducing concentrated heat almost to a mathematical exactness. Diathermy has comparatively no germicidal action, but in it we have a powerful agent in producing active congestion, in stimulating the artero-venous circulation to and from the part.

It is to be hoped that in the use of the various mechanical agents at our hand, we will not become lax or hesitant in the quick use of surgical means where such is needed.

DEATH FOLLOWING CAUTERIZATION OF THE CERVIX

By W. W. CROSS, M. D., Fresno, Calif.

INTRODUCTORY NOTE

Some stupid physicians who still claim to doubt that the practice of medicine is a hazardous vocation might learn lessons about safety of more than one kind by a careful perusal of this report by Doctor Cross.

That it is still easier to sell some doctors life insurance than it is insurance to protect health and reputation, is an inexplicable fact.—EDITOR.

This report is made because death followed a procedure usually considered free of danger.

I became familiar with the circumstances regarding this patient at the necropsy. The following information was obtained from the physicians who attended her during her illness.

Mrs. X applied to her physician April 21, 1925, complaining that she had an irritating vaginal discharge. She was 35 years of age, apparently in a fair condition of health. The physical examination failed to disclose significant facts other than those bearing upon the condition for which she applied for treatment. The vaginal discharge, according to the patient, had developed after the birth of her second child, who is now 18 months of age.

Examination revealed a vaginal discharge, irritation of the vagina and vulva, the skin of the thighs showed discoloration, apparently caused by the secretion, the cervix was red, lacerated, and had granulating tissue protruding from the opening.

Treatment consisted in an application of silver nitrate in a 25 per cent solution to the cervix, and an antiseptic douch prescribed for her use at home. The silver solution was used at intervals of four days. Twenty-two days following her first visit, menstruation occurred, according to her statement, and she was advised to have the cervix cauterized, as the local condition remained the same. She was examined by an associate, as well as by the physician in charge, and both were of the opinion she was not pregnant.

Cauterization of the cervix was performed with an olive-point electrode, the canal curetted, and the surface again seared over with the olive point, the canal loosely packed with iodoform gauze. This was done June 2; the gauze was removed June 4. The next morning, June 5, the patient had chills, fever, and a general appearance of

serious illness. At this time the husband became dissatisfied with the situation and discharged the physician.

From those who subsequently directed the treatment, it was learned that the patient had a temperature of 105, the circulation was embarrassed, and blood cultures were positive for streptococcus; white blood count, 6200. Death resulted on the eighth day following cauterization.

At the post mortem made the day following death, an examination of the abdomen and genital canal only was made. Upon opening the abdomen a moderate amount of gas was found in the intestine, the surface was smooth, normal in color and free from exudate, except over the surface of the uterus, tubes, and ovaries. In this area the surface was smooth, free from exudate, and glistening. The color was changed by a uniform red which traveled apparently along the course of the blood vessels; the uterus and appendages were not swollen or enlarged. These structures, including the greater portion of the vagina, were removed. When the genital canal was divided posteriorly, the cervix showed a slight discoloration, due to hemorrhage into the tissue. There was not evidence of trauma. The mucous membrane was smooth, red and free of any evidence of trauma; the cavity free of membrane or debris.

It is worthy of comment that the embalmer injured his finger during the process of injection, and died four weeks later from septic poisoning. As the husband became dissatisfied with the patient's physician, a change was made and during the time she was under treatment by the second physician the question of pregnancy was raised. Had pregnancy been present, a criminal proceeding undoubtedly would have resulted. Although cultures were not made from the cervix, it does not appear unreasonable to ascribe the patient's death to infection lurking in the tissues cauterized. The end of a normal delivery could have resulted in disaster, charged to faulty attention at the time of delivery. Repair of the cervix and perineum could easily be the exciting cause of a disaster. The making of cultures before simple repairs may be the means of avoiding serious complications in a simple procedure, usually free of concern to the operator.

Mattei Building.

Demonstration of Female Sex Hormone in Circulating Blood—R. T. Frank, M. L. Frank, New York; R. G. Gustavson and W. W. Weyerts, Denver (Journal A. M. A.), have been able to show that the female sex hormone is present at times in demonstrable quantity in the circulating blood. The hormone is present only in great dilution. From the blood of five sows in estrus and the blood of one bull, an alcohol benzene extract was made and injected into one or more castrated rats and the vaginal smear watched. None of the anestrus bloods, or the male blood, gave a positive reaction. Of the five bloods obtained from estrous animals, four gave positive results with a total dosage of 75 mg. of crude extract. With present methods of extraction, at least 300 cc. of estrous blood is necessary to obtain 75 mg. of extract necessary for the test. Even with the present crude and not quantitative methods of concentration, these results show that: (1) the female sex hormone can be recovered from the circulating blood, and (2) the quantity in circulation is greater during estrus than during the interval.

Underestimation of Good Results in Mental Diseases—The careers of 1054 consecutive patients admitted to the department for mental and nervous diseases of the Pennsylvania Hospital were studied by Earl D. Bond, Philadelphia (Journal A. M. A.), for a period of from five to ten years. The patients had the more severe mental diseases. Of 1054 consecutive patients admitted, thirty were lost. Of the 1024 patients that could be followed over five years, 274 recovered and stayed well; 159 improved greatly; 331 died, and 260 remained stationary or grew worse. Bond says that everything in psychiatry today points to the prospect of increasing the recovery percentage by getting at mental diseases early. If by getting at them late, consecutive cases may be expected to show full return to function in 25 per cent and amelioration in 15 per cent more, the general practitioner first, and the psychiatrist later, is justified in taking as hopeful an attitude as is taken for surgical problems.

EDITORIALS

The Lane Medical Lectures

The Lane Medical Lectures will be given in Lane Hall, Stanford Medical School, Sacramento and Webster streets, San Francisco, Monday to Friday, November 9 to 13, 1925.

Lecture 1, November 9, 1925—Congenital Dislocation of the Hip.

Lecture 2, November 10, 1925—Arthroplasty—History and General Considerations.

Lecture 3, November 11, 1925 — Arthroplasty — Technique.

Lecture 4, November 12, 1925—New Conceptions of the Pathogenesis of Sciatic Pain.

Lecture 5, November 13, 1925—The University of Bologna in the History of Medicine.

impetus which was destined to modify and vastly enlarge the field usually assigned to orthopedic surgery.

Doctor Vittorio Putti

On invitation of Doctor Ray Lyman Wilbur, President of Stanford University, these lectures will be given by Doctor Vittorio Putti of Bologna, Italy, one of the world's most distinguished orthopedic surgeons. Comparatively a young man, he is full professor at the University of Bologna, and has been since the year 1910 director in the Rizzoli Institute in that city.

When he was a student at the University of Bologna, the great name of Antonio Codivilla turned his attention to the newly founded Rizzoli Institute. The surgery of the limbs and, in a broader sense, of the entire motive system of the human body had received from Codivilla a novel

Part of Rizzoli Institute, with City of Bologna in Distance.

In the year 1910, Putti succeeded Professor Codivilla in the direction of the Rizzoli Institute, which

had become part of the medical school at the University of Bologna. During the war the Rizzoli Institute was made a surgical center for the care of the maimed and disabled soldiers. In its work-

was to manufacture the mechanical appliance so as to conform and possibly adapt the work of the surgeon to the mechanical demand of the instrument which was to be animated by the residual energies

Department of Upper Limbs Work.

Department of Lower Limbs Work.

shops thousands of artificial limbs were made under the direct supervision of the medical staff.

This intimate connection between mechanical and surgical science was an entirely new development in the field of Italian orthopedics. Having experimented and widely used the Vanghetti theory of cinematic surgery, Professor Putti always made a point of examining the stump with the artisan who

of the stump itself. The artificial limbs made at the Rizzoli Institute won the Gold Medal at the exhibits held in Paris and London.

It may be interesting to note that the workmen who made the wooden limbs were mostly experts in the carving of art furniture, a traditional Italian trade. The furniture was adorned by them with carved figures and ornaments which required a

knowledge of drawing and of anatomy which was turned to a useful purpose in the carving of artificial limbs. The visitor may also note with interest that reproductions of Leonardo's anatomical drawings are used as models in the Bologna workshop.

Putti has twice visited America, is an honorary member of the American Orthopedic Association, and has many friends and acquaintances among the leading surgeons of America.

In 1923 he visited South America and lectured extensively in Argentina, Brazil, Peru, and Chile. He performed several important operations in San Paulo and Rio, and *on his desire the honorariums which were offered for his professional service were given to the hospital.*

The Rizzoli Institute for Orthopedic Diseases is named after Professor Francesco Rizzoli, who bequeathed his entire fortune for its establishment. It is located in the former Monastery of the Olivetan Monks on the hill of San Michele, in Bosco, overlooking the city of Bologna. Besides the beautiful surroundings, the building in itself is of great interest.

The library is located in a hall adorned by frescoes of the sixteenth century. The oak-panelled room, used by the monks as a refectory, has been transformed into a pathological museum. On the floor of the long corridors and court, quaint inscriptions and astronomic signs are to be seen. The Institute can accommodate 200 patients, but the large halls and wide corridors allowed it to receive up to 1000 soldiers during the war.

Besides the wards, private rooms, and special departments for children, the Institute is equipped with gymnasium, library, scientific laboratories, museum, and orthopedic workshops. There is now a branch of the institution in Cortina d'Ampezzo, where at an altitude of 7000 feet the patients enjoy mountain air and heliotherapy.

The lectures and courses for students of the University of Bologna take place in the Institute itself, and are attended by medical students from every part of Italy as well as from many foreign countries, including North and South America.

LANE MEDICAL LECTURER

Thus we have before us a brief sketch of the man—and his background—who is to give the Lane Lectures for 1925. Not only orthopedic surgeons,

but physicians of all classes ought to attend these lectures.

Why not set aside the week of November 9 to 14, to hear, meet, and know Doctor Putti? Physicians from other localities will be able to spend all of their available time in interesting conferences with other medical teachers and colleagues in any of the splendid hospitals of the city.

EVERY DOCTOR A HEALTH OFFICER

President George E. Vincent of the Rockefeller Foundation said several mighty interesting things (L. I. Med. Jour.) in a recent address before the Kings County (New York) Medical Society. At least we find them interesting because they are along the line that CALIFORNIA AND WESTERN MEDICINE has been preaching for years. In effect they are, that permanent health progress will move ahead precisely as physicians practice.

President Vincent had become so interested in the gratifying reports about better health among the people of Denmark that he sent a representative to study the secrets of success. The summary of the representative's report President Vincent gives in this sentence:

"In Denmark every doctor is a public health officer, and every public health officer is a doctor."

There was only one full-time public health officer in Denmark. There were no "Clean-up weeks," "tag days," "sales of seals," nor "vociferous campaigns of education." The writer goes on to say that the "limits of public authority (in health matters) are coming to be recognized." Precisely, and it is here—as always—that the *personal health doctor* is again being discovered as *public health doctor* upon whom the health progress of persons and masses unavoidably devolves. There is too much ballyhoo about health by people who do not and cannot know what they are talking about, and one of the chief results of their activities—whether or not so intended—is to lead average citizens to think less of the ability and usefulness of their doctors who do not utilize circus methods to promote their cause. As President Vincent points out, we are only beginning to appreciate that our boast of great, highly effective fire departments is made "without

realizing that the very need for them is a national disgrace." Some day—maybe—we will develop the same intelligent consciousness about "great public health departments."

However, we are now in a much earlier stage of development in health promotion, and we may continue to expand our fire departments of health until reaction comes and returning sanity again reveals the simpler, cheaper, and more effective method of the individual and family "health counselor." There is a place for organized public health, and there is plenty for such organizations to do. There is even a place for the public health "OFFICER," and there is great need for the public health DOCTOR. The distinction between "officer" and "doctor," as here used, is important and significant: Society needs more health *doctors* and fewer health *officers*. The public health doctor never forgets he is a *doctor*, and many health *officers* never have been doctors in the sense we mean, or, if so, they have forgotten the fact.

WHO FILLS YOUR PRESCRIPTIONS?

Ignorance, mistakes, or worse, on the part of pharmacists and other technicians who fill doctors' prescriptions are reflected with increasing frequency in the public press. Now it is substitution of corrosive sublimate for calomel; then it is inaccurate weighing and consequent overdosage; here it is wrong technique in preparing arsenicals, toxins, antitoxins or other dangerous substances, and there it is some other tragedy from some other form of carelessness, irresponsibility, or worse, on the part of the dispenser.

The doctor's duty is not ended when he writes an order or gives a prescription. He should satisfy himself that his instructions will be carried out by directing the patient, if need be, where he can find reliable service. True, most people once felt they could rely upon the state's license for such service, but it appears that this is now no more reliable in many places as to pharmacists and dispensers of doctors' prescriptions than is the state's license to practice medicine a guarantee of the honesty or ability of a doctor.

Newspaper stories are entirely too numerous of instances of poisoning by "wrong mixtures," "overdosage," substitution or what not, by narcotized, criminally negligent, ignorant, or mentally ill technicians who prepare dangerous supplies for doctors and their patients.

Nothing in this editorial is intended to reflect upon the great majority of prescription pharmacists who are rendering well a necessary service and upon whom physicians and the public rely with confidence. It is their interest as well as that of physicians, and more important still that of the public, that warrants this caution.

DIAGNOSTIC ERRORS

Of all the stupid traditions that hang onto and around the practice of medicine, there is none worse than that old and long since outgrown practice of trying to find some *one* disease that would explain all of the patient's symptoms and then looking no further *before* acting. Then if anything else should show up later, or if the symptoms continued after

the cure, to blame it all upon "complications sequelae or secondary disease."

Only a few years ago, given a patient with a leaking heart valve, and gall-bladder pain, much time was wasted in trying to make one of them the "primary or principal disease" and the other as "secondary or a complication." Too much of this sort of stupidity is still reflected in some hospital and morbidity records.

A great medical teacher has said that he could satisfy himself as to efficiency and thoroughness of a hospital or a physician by the number of **different** diagnoses found in each patient. "*Not primary and secondary complications and sequelae, but diagnoses.*"

The average number of diagnoses in large series of adult patients will show—and some of them do show—from two to six or even more separate troubles for each patient. Of course, there are secondary troubles and complications directly resulting from some other disease. *But this is not the important point from the standpoints of either preventive, ameliorative, or curative effort.*

Such narrow appreciation of the fundamentals of medicine, combined with a certain amount of carelessness, is responsible for a certain amount of unnecessary surgery and other forms of medication. This story and its consequences are seen and recognized by most physicians. It is reflected in many of the scores of letters that pour in daily to the Better Health Service. Patients by the hundreds during the last year have told their troubles, which may be illustrated by one: The patient complained of vague digestive symptoms. Physician's examination showed some tenderness in the right abdomen. The appendix was removed. The symptoms continued. The gall-bladder was removed. The symptoms still continued. The pelvis was examined, and some trouble found. The uterus was placed and fixed. More of the same and, of course, other symptoms. A neuropsychiatrist found a definite neurotic background, and made a diagnosis of hysteria. Appropriate treatment does all that could be done, considering the years of misapplied effort. It does all that was indicated at any time during the patient's illness.

Every physician can tell many stories to the same general effect. A larger proportion of patients than formerly now recognize that physicians make human errors, and more and more intelligent people are judging a physician by his education, his humanity and, above all, *by the earnestness and thoroughness with which he applies himself to his problems.*

Clinical and Serologic Studies of Neurosyphilis With Tryparsamide Therapy—In a series of thirty-seven cases of neurosyphilis, in all of which anti-syphilitic treatment had been given previously, tryparsamide therapy combined with special technic has proved, in the hands of J. M. Wolfshon and Carlos Leiva, San Francisco (Journal A. M. A.), an apparently distinct advance over other forms of treatment. The improvements are mostly symptomatic. Tryparsamide in doses of 2.5 gm. may and does occasionally cause ocular symptoms, but no more often than do other arsenicals. It is one of the best tolerated of the arsenicals used in the treatment of neurosyphilis. It has little or no effect on the serologic reactions in general paralysis. It is distinctly beneficial, both clinically and serologically, in certain types of tabes. Tryparsamide is a distinct addition to the therapy of neurosyphilis.

The Month With The Editor

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

That the Roving Searchlight of health "uplift" is already turning its glare elsewhere and leaving the "periodic health examination on your birthday" propaganda in the shadows, is obvious.

This has been anticipated by intelligent thinkers from the beginning because:

(1) As Lord Dawson, physician to the British King, is widely quoted as saying, the "card index" type of insurance or other machine examination proposed by "uplifters" or those with a financial interest in the person's health is of little value.

(2) Many medical magazines, including CALIFORNIA AND WESTERN MEDICINE, have iterated and reiterated the fact that a health examination of itself is of no value and often does harm. Diagnosis is only one link—and an inseparable one—of many that make a chain that may promote health.

As Doctor Dawson so well says, if periodic health examinations are conducted by other than the person's own private health counselor they "only produce periodically a great amount of anxiety that may do any good otherwise achieved."

Doctor Have You Read that illuminating editorial headed "Oculists and Optometrists," published in the Journal of the A. M. A., July 25, 1925?

Are you following the developments in this problem in other scientific and general publications?

There is nothing complex or obscure about the problem, but its unfolding is worth following closely, particularly by those who are in danger of getting hurt.

The Attorney-General of California has ruled, according to press reports, that optometrists "may not use the prefix 'Doctor.'"

One writer suggests that "Doctor" might be substituted for by "Doptor" for the optometrists.

It is further suggested by the same author that the coinage of a new word might be helpful to the department of physics of the University of California in their embarrassing competition with the school of medicine of the same university, in the "preparation" of persons to "diagnose and treat the diseases and infirmities of human beings."

Skilled technicians, whether called opticians, optometrists, or by whatever title, are essential and useful persons. The state should see to it that they are licensed upon a basis of sufficient education, intelligence, and technical training to accurately fill the prescriptions of an oculist.

A good optician—or optometrist—should have precisely the same relation to an oculist that the well-trained technician in any other branch of medicine has to the physician. This is all that their background education and experience warrants their undertaking, and if any want to do more, they should first secure the much more difficult education of a physician.

"SCIENCE AND LEARNING have outpaced our populace," Doctor Wilbur announced in his Pennsylvania University Day address. Astronomy is accompanied by its popular imitation, astrology; medicine has its great shadow-land of buncombe, deceit and plausible foolishness and chicanery.

"One would think," continues Doctor Wilbur, "that a sense of humor alone would keep our fellow-citizens from thinking it possible that the stars in their courses were interested in the welfare of their livers and the success

of their love affairs, but it takes time and much education to cultivate more than the surface of the ordinary human mind."

"A considerable part of our so-called cultural education is about as genuine as Santa Claus."

"Rustling, not rusting, is needed to improve a good mind, and no amount of action on the screen can develop the body muscles of the onlookers."

The Shining Exception—"Did any of your family ever make a brilliant marriage?"

"Only my wife."

"WE FAIL TO REMEMBER," believes J. E. Sweet (Ohio Medical Journal), "that all research work in medicine starts with the patient, and will ultimately revert to the patient when the answer is found."

"It is easier for the patient today to put him into a Ford and transplant him fifty or seventy-five miles to the nearest hospital than it was fifteen years ago for him to wait while the old farm horse plodded to the village, to find the doctor thirty miles away in the other direction."

We Saw in Print recently a statement that the "school children of Los Angeles are treated by the school nurse after the physician has made the diagnosis."

Draw your own conclusions.

Another Attack of Eugenics—

"There's been quite a rumpus in the school yard. What is it all about?" asked the professor.

"Why," explained Harold, "the doctor has just been around examining us, and one of the deficient boys is knocking the stuffings out of a perfect kid."

"A CURIOUS WORLD devours news of politicians maneuvering their nations into wars, but skips over the news of still greater wars always going on at the outposts of civilization. There, where deadly enemies knowing no creed or boundary lines stand always at the gate, the army of medical science fights on without truce. . . . On every front, on every advanced line, medical science fights on for humanity going its heedless way."—San Francisco Chronicle.

When great metropolitan newspapers editorialize statements like this we feel that progress is broadening.

Statistics—

Old Uncle Eben Jones went into a life insurance office and requested a policy.

"Why, uncle," said the president, "you are too old for us to take the risk. How old are you?"

"Ninety-seven come next August," said the old man, and added testily, "If you folks will take the trouble to look up your statistics, you'll find that mighty few men die after they're 97."

"Pre?" Pre? Pre pre!—We have pre-ed most everything from birth to death.

Now comes the latest "broadcast," in which a life insurance company devotes pages to what they call "Pre-symptoms"!! Constipation is listed as one of their pre-symptoms. YE GODS!!

IT WOULD BE SAFE to wager that the editor of the San Francisco Chronicle received a hundred letters of protest about that paper's very fine editorial about cancer quacks.

We need more newspaper editors who will make statements like the following from the Chronicle editorial, and

who will at the same time apply the same policy to their advertising pages:

"Cancers have yielded to the surgeon's knife, but only in the hands of skillful men, and these will be found always to be reputable and ethical practitioners. . . . When there is a known cure it will be found by reputable men, and they will not keep it a secret. It will be given to the whole medical world, and for no selfish, financial motive. Anyone who claims to have discovered a short cut to a cure and uses it for profit reads himself out of the fellowship of decent men. He is a quack and a very cruel one."

The announcement that Doctor Rosenow "advances the hypothesis" that hiccough may be caused by streptococci leads a writer (Practical Druggist) to pen the following lines, which Dudley Smith enjoyed so much that he suggests we pass them along:

THE HUMBLE HICCOUGH

In days of old when beer was sold
At costs extremely low,
We used to think that it was drink
That made us hiccough so;
But now the news that we peruse
Informs us but to mock us
That every hic proclaimed us sick
And bit by streptococcus.

What time his spouse would greet a souse
That kicked him home a-blinking
And, features grim, would say to him,
"Adolphus, you've been drinking."
Ehu! 'twas then the good days when
'Twould have been worth the money
To say, "Th' bunk! No, I'm not drunk,
I'm streptocockeyed, honey!"

"S. S. S." one time widely recognized as the pseudonym of a patent medicine, later as a signal of distress, is now being more or less extensively interpreted as "Sob Sister Stuff."

There seems to be a chance that these "Sob Sisters" may concentrate their "excess of emotional perspiration," commonly called the "milk of human kindness," on evolution.

This will be helpful to many good causes they now embarrass, and evolution is a more harmless toy for them to play with than is the more prosaic question of health.

Dramatizing health essentials is much like dramatizing the Ten Commandments; it is a hard uphill pull, and no rest stations.

The way the pendulum is now swinging, the first thing we know the health centers and hip-hurrah methods of medical practice will be as dead as the stupid "health clown" propaganda and "Little Willie" health stuff of a few years ago. A lasting impression was made upon many by some ungainly "health fairy" dressed in white, exposing in her contortions the unappetizing movements of flabby oversized calves, unwieldy and flappy abdomen and heavy, pendulous breasts.

Well, it's about over, and many of the chronically ill and otherwise handicapped are forced to go back to doctors and nurses for services. So be it!

"SO FAR," says President Vincent of the Rockefeller Foundation, *"the outlook for the general practitioner in the United States is still cheerful."*

Encouraging deduction that, which the writer supports by declaring that it is a "serious fallacy" to say that "poorly trained professional people go to the country. *They are safer in the city.*"

Evening Up—He—"Is she progressive or conservative?"

She—"I don't know. She wears a last year's hat, drives a this year's car, and lives on next year's income."

AN EASTERN NEWSPAPER in discussing one of our California homicide trials concludes that "it's a poor alienist that won't work both ways."

It seems to us unfair, in view of recent history, for a Chicago paper to pick on California alienists.

"A NEW LAW is presented which will give the owner of a piece of ground the right to charge aviators for the use of the air above it.

"We knew that someone would soon invent a way for charging for the air you breathe. The only two free things left in the world were air and the doctor's time at the clinic. And now the air is to be collected for, while the physician still hustles down to the clinic to bestow his generosity on foreigners with rags on their backs and gold under the hearthstone at home!"

"THERE IS NO CREAM IN CREAM OF TARTAR, no grape in grapefruit, and no milk in milk of magnesia." However, there is bull in Bull Durham, Pathis in Osteopathy, and Tics in Chiropractics.

Comments—I wish to thank you for the attention which you have given the papers of Dr. Wisner, formerly of our group. They have been published in nice style, and we appreciate the editorial comment. I have sent a copy of the Journal to President Pritchett of the Carnegie Foundation.—F. V. Simonton, Chairman California Stomatological Research Group.

I See by the Papers That—

Annie Laurie, one of the most effective of newspaper writers, has been using her "lancet" upon the "Elixir of Youth—again" crowd.

She takes as her text Steinach's "latest" of many "discoveries," which should have occupied advertisement space, but which his representatives succeeded in selling as news.

"Who will believe," asks Annie Laurie, "that Steinach's new elixir of youth, for sale at so much a hypodermic, will make young again old ladies whose brains stopped growing at sweet sixteen; old men in their second childhood; pitiful old wives and pathetic old husbands."

Hundreds of thousands, and even millions, will believe, sacrifice and buy." What?

The number of stupid suckers would be materially reduced if our well-intentioned editors would make these propagandists pay for their space just as they do the "junior Steinachs" who, like the poor, are always with us.

—Two California doctors are defendants in a \$500,000 damage suit. According to the story, such a severe infection followed an operation for the removal of "surplus flesh" about the ankles that both legs had to be amputated. Now the patient wants half a million dollars for alleged "negligence."

Another doctor is defendant in a malpractice suit because a local infection and an ugly scar followed an ordinary intramuscular injection.

Still another doctor is charged with malpractice (negligence) because of injury produced by infiltration of salvarsan into the tissues about the arm vein.

As we have stated repeatedly, the practice of medicine is constantly growing more hazardous. The physician who does not protect himself and those dependent upon him against unavoidable accidents is not deserving of any special sympathy.

—Another Doctor Gets His Picture and scraps of an "interview" prominently before the public by claiming that "women are 20 per cent crazier than men." Of his last 15,000 "cases," "60 per cent were women."

Some papers charge space rates for "news" (?) of this character.

—Bishop Fiske (American Mercury) takes an awful "swat" at "organized commercialized social service." No matter what one's convictions may be, it is well worth while to read what the ever-growing group of writers—of whom Bishop Fiske is only one—have to say about placing humanitarian and spiritual services, which the Master called charity, upon a "business basis."

Persons who have openly repudiated the Old Testament and have given us a variety of versions of it to suit this or that group are on the road to similar actions with the Gospels. Jesus Christ, in speaking of charity

said, "Let not your left hand know what your right hand doeth."

Modern "experts" organize charity upon a "business basis" and designate their organizations as "voluntary government."

I wonder.

Chiropractors are not "legally qualified physicians" within the meaning of a health insurance policy, according to a ruling of the Supreme Court of Wisconsin, in the case of *Jake L. Isaacson vs. Wisconsin Casualty Association*. The plaintiff, while sick, submitted to treatment by a chiropractor for part of the time. The policy provided that he could make claim only for the time he was treated at least once a week by a "legally qualified physician." The Supreme Court decision was a reversal of the lower court's judgment.—Underwriters Report.

"The Legion News," the official publication of the California department of the Legion, editorially drastically criticizes doctors for opposing the Reed-Johnson Act. Several members have sent in clippings of an editorial which makes the statement, among others, that: "From the medicos' point of view, a soldier is entitled to little or nothing from the country he helped preserve during the trying period of war. From their standpoint it might be well to have frequent wars in order to build up a lot of work for our country doctors that they might better make a living."

One might think from this untruthful statement that none of our doctors were veterans. As a matter of fact, no other vocation enrolled such a high percentage of its members nor made greater sacrifices for our common cause.

The Legion News editor is unfair to a large group of the members of his own organization in thus attacking so viciously their principles, motive, and integrity.

As to the Reed-Johnson bill, unless we mistake the signs of the times, it is destined to travel the usual stormy road of socialistic schemes.

IF THE NUMBER OF COPIES of a form letter of the "Life Extension Institute, Inc., of New York," sent in to us with marginal notes, are indicative, this corporation's methods "as middlemen" in the practice of medicine in California are causing both them and the doctors some concern.

The letter in question purports to be "a correction of misstatements about The Life Extension Institute Incorporated."

The two paragraphs of the letter which have aroused the ire of some of our members, and which have "tickled the funny bone" of others, read:

"Reports have been circulated in medical circles to the effect that the Life Extension Institute buys examination reports from physicians and then sells the information received to insurance companies for higher fees.

"The facts are these: The Life Extension Institute contracts with insurance companies for service to policyholders. This service includes a medical examination, for which a fee is paid to the physician. The remainder of the fee received from the insurance company is used to pay for the other phases of health education service rendered to policyholders." (The bold face is ours.)

Read the charge and the reply again. It's interesting AND illuminating. Several of our correspondents ask if the corporation's admission that there is a "remainder of the fee" does not constitute an admission of the charge that they "buy at one price and sell at another."

One of our members comments upon this point thus: "I didn't larceny nothing; I just stole the hawg."

Another correspondent pencils this limerick on the margin of his copy:

There was a young lady of Niger
Who smiled as she rode on a tiger;
They came back from the ride
With the lady inside
And the smile on the face of the tiger.

MALPRACTICE SUITS are being reported against physicians for accidents and results following the use of anesthetics in the doctor's office.

There is no law that prevents a physician's anesthetizing a patient in his office. But when he does so, he

assumes moral, professional and legal hazards that most doctors prefer to avoid. The doctor who assumes such responsibility should at least protect his family by adequate liability insurance.

IF THERE REALLY ARE TIMES when ignorance is bliss, they assuredly do not include the ominous moments when a wily *beauty specialist* permits the life-killing rays of short wave length to impinge on the bearded skin of his unsuspecting victim.—Editorial, Journal A. M. A.

That the Way of the Transgressor Is Hard is just as true for the advertising, propagandizing, "interviewed-by-force" doctor as it is for the near doctor who sells some form of "hot air" as a panacea.

What happened to "Dr. Leonard Keene Hirshberg, A.B., M.A., M.D. (Johns Hopkins University)" is a good sample illustration; for details, see editorial Journal A. M. A., August 1, 1925.

TODAY, LIFE CALLS for physicians who are men of character, clean men, with honest self-sacrificing devotion to humanity and to truth. Equanimity, humility, and sympathy should dwell in the spirit of one who attends the suffering.—Editorial, Atlantic Medical Monthly.

"BETTER HEALTH" is now being broadcast by the Gorgas Memorial Institute as "*The Gorgas Idea*." This, in spite of the fact that "Better Health" has been for years protected by usage and the copyright laws as the title and working slogan for progressive health work emanating from California. The Gorgas Institute people know this, and we wonder how much further they will go in appropriating to their own use the property, by usage and law, of others.

DOCTOR OTIS ALLEN SHARPE writes us that he has suffered "chagrin, ridicule, and much damage" from recent unauthorized publicity about some of his work in certain newspapers.

The articles *did* read much like some of the illustrated interviews with "great goat gland specialists" that have "Advt" placed inconspicuously at the bottom.

We don't blame Doctor Sharpe for repudiating the whole thing, and hope he will persist in his present plan to seek legal redress.

From the Medical Press—

—Doctor Benjamin Kramer (Am. Jour. Dis. Children, August) claims to have cured eight children suffering from "active rickets" by the administration of "irradiated milk." His methods are described.

—Doctors Samuel J. Levin and John P. Parsons (Am. Jour. Dis. Children, August) found the skin "blanching test" of Schultz-Charlton effectively and specifically diagnostic in fifteen cases of scarlet fever. Evidence given in detail.

SHOULD DRUG ADDICTION be a reportable disease, we are asked. This is an important question, and we would like to have your answer to it.

If drug addiction is a disease—and it undoubtedly is—it certainly is a dangerous one, and communicated rather indiscriminately. Might not placing it upon the reportable list serve a useful purpose?

Treatment of Intracranial Hemorrhage in the New-born—Clifford G. Grulee, Chicago (Journal A. M. A.), feels that in the present state of our knowledge the best treatment for intracranial hemorrhage is absolute quiet and rest; that the measures up to the present time adopted for the relief of the condition are satisfactory neither from the theoretical nor from the practical standpoint; that the damage is done before the measures can be of value, and that, as a consequence, until a diagnosis is made much earlier than seems at present possible, the best plan to be followed is to see that nothing is done to disturb the quiet of the infant.

Medical Economics and Public Health

These Gems are quoted from widely published extracts of an address by a professor of a much heralded school of public health.

This professor, who is teaching doctors to be "public health officers," tells the world that the chief medical service of the future "will center about the county hospital" with a "full-time salaried staff" for the hospital "and clinics."

This state medicine—or more correctly, county medicine—center will serve "all the seriously sick of the county"; "maternity cases" and all those suffering from "obscure and chronic complaints."

"Private practitioners," according to this paragon, will be "mainly concerned with the health supervision of their patients." Even these "private practitioners" will be paid upon an "annual fee basis" and all the health work of a county will be regulated by a "medical director" responsible to a "board of trustees."

This speaker and the school he represents are not alone by any means in the apparent renewal of efforts to sovietize health in the United States.

The Pacific Coast Conference of Health Officials and the annual convention of the Health Officers of California meets at Long Beach, California, September 28 to October 3. Dr. F. W. Browning, Hayward, California, is secretary-treasurer of both organizations.

The United States Public Health Service Wants More Doctors—Applicants must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written and clinical tests before a board of medical officers, and undergo a physical examination.

Examinations will be held in San Francisco, September 14. Further information may be obtained from the Surgeon-General, U. S. Public Health Service, Washington, D. C.

New Health Officers Receive Appointment—According to the California State Board of Health Bulletin, the following appointments and changes have been made recently:

Dr. E. B. Philbrook has been appointed health officer of the city of Santa Cruz to succeed Dr. W. H. Congdon. Doctor Philbrook is licensed to practice medicine and surgery in California, but is not a member of the California Medical Association.

Dr. Charna G. Perry, a member of the California Medical Association, succeeds Dr. Allen H. Vance as city health officer of Sausalito.

Dr. R. C. Main, health officer of Monterey County, has taken over the public health administration of the cities of Pacific Grove and Monterey, both of which municipalities are now included in the county health unit.

Mr. M. B. Ordway was formerly health officer of Pacific Grove, and Mr. H. R. Alexander of Monterey. Communications should be addressed to Dr. Main at Salinas or Mr. Clyde L. Dorsey, deputy health officer, Monterey. Doctor Main is licensed to practice medicine and surgery in California. He is not a member of the California Medical Association.

Dr. Smith McMullin of Yuba City has been appointed health officer of Sutter County, succeeding Dr. W. L. Stephens of Meridian. Doctor McMullin is a member of the California Medical Association and is licensed to practice medicine and surgery in California.

Dr. F. W. Townsend of Loyalton has been appointed health officer of Sierra County, filling an office which has been vacant for several months, following the departure of Dr. A. O. Eckhardt. Dr. Eckhardt is a member of the California Medical Association, but Doctor Townsend is not a member.

Mr. Edgar A. Miller has been appointed health officer of the newly incorporated city of Tujunga in Los Angeles County. Mr. Miller is not licensed to practice medicine and surgery in California.

Mr. F. A. Beggs has been appointed health officer of Signal Hill, succeeding Dr. Arthur E. Pike. Mr. Beggs is not licensed to practice medicine and surgery in California, and is not a member of the California Medical Association.

Dr. H. S. Gordon has been appointed health officer of Perris, succeeding Dr. D. W. Sheldon. Doctor Gordon is not now a member of the California Medical Association, but is licensed to practice medicine and surgery in California.

Encouraging Types of Advertising—Physicians of Southern California will shortly receive a brief circular from M. J. Benjamin regarding his "Natural Support for Hernia." Mr. Benjamin is an advertiser in CALIFORNIA AND WESTERN MEDICINE, and the encouraging feature of his other advertising matter is, that he voluntarily submits his "copy" to the California Medical Association for acceptance *before* he issues it.

In a letter Mr. Benjamin says: "I am prompted to submit this to you because of my being an advertiser in CALIFORNIA AND WESTERN MEDICINE and *because of my desire to conduct my business along ethical lines*. If there is anything objectionable regarding this form of advertising or the copy used, I will be glad to change it sufficiently to make it acceptable."

Several of our advertisers have adopted similar practices, to the interest and advantage of the public health, and, we firmly believe, to the financial advantage of the honest vendor of honest goods.

A working monograph on the treatment of syphilis, prepared by the Dermatological Research Laboratories, will be sent with the compliments of the publishers to any physician requesting a copy.

The introduction discusses arsphenamine vs. neoarsphenamine, sulpharsphenamine, bismuth, and mixed treatment.

Chapters are devoted to methods of treatment: Intraspinal injections; technic of preparing; arsphenamine; neoarsphenamine; sulpharsphenamine, and bismuth; possible reactions and sodium thiosulphate.

Requests for this monograph should be addressed either to The Abbott Laboratories, Chicago, or the Dermatological Research Laboratories, Philadelphia.

For the Convenience of Physicians located in the Eastbay region, the Travers Surgical Company has opened a store at 435 Nineteenth street, Oakland, telephone Oakland 343. The increased patronage of the members of the C. M. A. across the bay has made this possible. The same complete stock of supplies is carried in the Oakland store as has always been found in the San Francisco store, and the same service is rendered. The advertisement of this popular surgical supply house is always found in each issue of CALIFORNIA AND WESTERN MEDICINE, opposite the last page of reading matter, as their contract calls for this "preferred" space.

Imitation may be the Sincerest Form of Flattery, but when it enters the health field, whether as a medical organization, publication or what not, it may prove dangerous to the unwary.

We now have several imitators of Better Health magazine. Some have contented themselves with appropriating the copyrighted title, while others carry the imitation to fake better health services.

There are all sorts of fake "national" medical and research organizations that make their names and general procedures sound as much like the genuine as they can or dare. This obviously for the purpose of fooling the public.

The "National Health Service," an organization with something to sell, approximates our "U. S. Public Health Service" so closely in name that Surgeon-General Cumming has "released" a statement denying that the Gov-

ernment has any connection with the "National Health Service."

"Orders From Washington have stopped the sale of confiscated liquors to doctors, druggists, and hospitals."

An energetic doctors' supply house broadcasts this information, and at the bottom of their letter invites a telephone call for prompt service.

But oh, what a difference in the price!

The Anglo-French Drug Company take their place in this number along with our other accredited ethical advertising firms who invite the confidence and support of our members. Their new offices are in the Flood building.

Alum Rock Sanatorium—Dr. Charles P. Durney, who has been active in tuberculosis work in the Hawaiian Islands for the last fourteen years, and who is head of the Government Sanatorium at Kula, Maui, T. H., has accepted the position of resident medical director of the Alum Rock Sanatorium, and will be associated with the staff in developing its growth as an institution for the care of patients suffering from lung diseases and tuberculosis in all its forms.

The Sanatorium has recently added a new wing of eight private rooms, and has completely rebuilt the culinary department.

"Should Pay for Treatment."—"The more I see of the way people spend their money," says "A Red Cross Public Health Nurse" in the Pacific Coast Journal of Nursing, June, 1925, "the more I am inclined to question, as do the doctors, the wisdom of some of our work."

Electrocoagulation and Radiation Therapy in Malignant Disease of the Ear, Nose, and Throat—Electrocoagulation in the treatment of malignant disease of the ear, nose, or throat, according to George E. Pfahler, Philadelphia (Journal A. M. A.), will have only a very limited field of application. Electrocoagulation consists in the destruction of the disease by coagulation of the tissues. The heat is caused by the resistance in the tissues to the flow of the high frequency electricity. It differs from the destruction by cautery; it is not a transmitted heat, but is heat generated in the tissues and extends to a greater depth than that of the cautery. It destroys all kinds of tissue in its path, and, therefore, cannot be used where blood vessels, nerves, bone or other essential tissues must be preserved. It is a painful procedure and must be used with either local or general anesthesia. If the area to be destroyed is supplied by large blood vessels, these arteries must be ligated in advance for fear of a secondary hemorrhage when the slough separates. There is always a sloughing process which will continue for several weeks or months, until all the dead tissue has been thrown off. If bone has been destroyed, it will suppurate, and generally separate as a sequestrum. Electrocoagulation can be used wherever the cautery can be applied and often also in very small areas where only a single wire can be introduced. It must be used under the guidance of the eye, and much skill is required in order that the tissue may be destroyed to the proper depth. Tissue can be destroyed by plunging the needle to any depth, but this demands skill, experience, and an accurate knowledge of anatomy. Radiation, on the other hand, has been used extensively with good results. Radiation can be used to advantage preceding operation, following operation or independent of operation, and should always be used in conjunction with electrocoagulation.

The Use of Antimony and Potassium Tartrate in Trichinosis—In a case cited by J. S. Grove, Chicago (Journal A. M. A.), very small doses of antimony and potassium tartrate proved effective; 1 cc. of a freshly prepared 2 per cent sterile solution was given intravenously. The next day 2 cc. of the 2 per cent solution was given intravenously. Following this the patient began to feel much better, and her temperature dropped to normal levels. On the third day, 3 cc. of the 2 per cent solution was given; on this day the patient developed slight muscular tenderness over the biceps brachii. On the fifth day, 4 cc. was given. Three days later the patient was well.

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
W. T. McARTHUR, M. D.....President-Elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

MEETING OF THE COUNCIL, C. M. A.

The next meeting of the Council of the C. M. A. will be held in Dining-room No. 3 of Hotel Biltmore, Los Angeles, September 26, 1925.

An open meeting will be held in the same room at 8 o'clock that evening to discuss industrial medicine and other subjects of general interest to members.

C. M. A. REVISING EXTENSION LECTURE PROGRAM

A revision of the Extension Lecture program of the California Medical Association is in progress. Every lecturer on the present list of speakers has been invited to revise the titles of his lectures at this time and submit the revised program to this office for publication.

Any member not on the present list who desires to be included in this service should at this time furnish the State Association's office his name and program. When lantern slides are used to illustrate lectures a notation to that effect is helpful. Lecturers are permitted the use of the Association's lanterns in this service, and may secure them from the office, 1016 Balboa building, between the hours of 9 a. m. and 5 p. m. daily, except on Saturday, when the office closes at noon.

It is earnestly hoped that interest in the Extension program will be stimulated by the submission of an enlarged and varied program.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert S. Thomas, secretary) — Since our last report in August we have had three new applications for membership. These will be presented at the September meeting. They come from E. P. Moser, Camino, Calif.; Charles G. Reynolds, Repressa, Calif.; Hans F. Schlueter, Sacramento, Calif.

The recent death of J. F. Sigwart, which occurred during the doctor's visit in San Francisco, came to us as a shock from a clear sky. He was a comparatively young man, in apparently perfect health. The heart of our Society goes out to his parents, Mr. and Mrs. J. A. Sigwart.

Sacramento and its close neighbor, Mather Field, have been assigned two hospital trains and two medical laboratories by the Allocation Board of the Ninth Corps Area. Once again, let me call your attention to the desirability of having our Society take an active part in comprising the professional personnel of these outfits.

It is pleasing to see G. W. Dufficy again making active rounds at the Sisters' Hospital. He spent a lengthy period in San Francisco in a post-operative convalescence.

Leo W. Farrell has continued as the resident surgeon at the Community Hospital.

Mervyn F. Frandy is now located at Jackson, Amador County. He goes there from Placerville.

With the coming of fall, the Society again starts its monthly meetings. The September meeting will be devoted to a roentgenologic symposium.

SAN BERNARDINO COUNTY

San Bernardino County Hospital Accredited by the Council on Medical Education and Hospitals of the A. M. A.:

Dear Doctor Musgrave—We are pleased to announce

that the San Bernardino County Hospital has been placed on the list of hospitals approved for internships. Copy of the Council's letter to Dr. Tisinger, the superintendent, follows:

"It is a pleasure to inform you that the Council on Medical Education and Hospitals has carefully considered your application, together with the recommendation of Hospital Betterment Service Bureau of your state, and has placed the San Bernardino County Hospital on the list of hospitals approved for internships. A notice of this recognition will shortly be published in The Journal of the American Medical Association.

We trust that this will be taken as an expression of confidence on the part of the Council and a sincere desire to be of any assistance to you in the future development and usefulness of the institution.

Very truly yours,

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS.

Per Homer F. Sanger."

❧

SAN DIEGO COUNTY

San Diego County Medical Notes (reported by Robert Pollock, M.D.)—The Alpine Sanitarium for the treatment and education of the tubercular, located at Alpine, California, is now under the general superintendency of Bryant R. Simpson, M.D., formerly in charge of the U. S. V. B. Hospital No. 64, Camp Kearney, California. Dr. Simpson employs a full-time specialist in tuberculosis as a house physician.

As a guarantee of the character, equipment, and service afforded, it has been passed upon and has secured the endorsement of the Council of the San Diego County Medical Society, as well as the San Diego County Hospital Commission. The admirable location of this institution in the foothills, with one of the most equable climates in Southern California, will undoubtedly make of it a very desirable place to which we may refer our tubercular patients.

Dr. Will H. Potter and Dr. Marjorie J. Potter have returned from the clinical tour of European capitals, which they much enjoyed.

The fall scientific program of the Medical Society shows a number of interesting meetings, starting with the annual visit to the Imperial County Society, which meeting will be held at the Barbara Worth Hotel at El Centro.

❧

SAN MATEO COUNTY

San Mateo County Medical Society (reported by W. H. Murphy, secretary)—At the July meeting of the San Mateo County Medical Society a fee schedule was presented by a special committee and adopted by the Society. Fees for general practice, including office and home work, obstetrics, surgery, gynecology, orthopedics, laboratory work, and genito-urinary treatment were set. The Society also adopted a placard to be posted in each physicians office, stating the fees for the more common forms of medical service. The plan in general was modeled after that used by the Tulare County Society, data upon which was furnished by Dr. John N. Blood of Redwood City, who formerly practiced at Exeter. No attempt was made to regulate the fees for eye, ear, nose, and throat work, it being the feeling of the Society that these should be set by the men who specialize in these lines.

The matter of establishing a credit bureau in connection with the Society was also presented, but it was decided to leave this matter in the hands of the individual practitioners. A credit bureau operating in the county offered to handle the work for the Society at a flat yearly rate per member, providing all members would adopt the plan. As unanimous consent to this could not be obtained, it was decided to let the credit bureau work with the members individually.

Walter M. Dickie of the State Board of Health addressed the Society at a special meeting on the evening of August 13 on the topic of full-time county health boards. At the July meeting a motion favoring the co-operation of the Society in such a movement was unanimously passed, and it was decided to request Dr. Dickie to talk to the Society so as to familiarize the organization with the details of the plan. Dickie discussed the advantages of forming a full-time county board and the

methods by which it might be done. He also spoke of infant mortality in California, and brought out the fact that in most counties a large amount of money is being spent yearly on health work with little results, due to the lack of proper organization and supervision.

Following Dr. Dickie's speech, the point was brought out by members of the Society that at present many "lay" organizations in the county are fostering the plan of a county health board, and that these bodies should have support and leadership from the county society. In order to further this plan, a committee was appointed to co-operate with such organizations. Members of the committee are F. Holmes Smith, San Bruno; W. C. Chidester, San Mateo; and W. H. Murphy, Redwood City.

At the present time the Society is carrying on work to familiarize the various interested organizations of the county, as well as the public at large, with the fact that the Society is behind the movement in question, and ready to lend it full support. The co-operation of the district attorney is also being requested in the legal aspects of the movement.

Harper Piddicord, formerly of Fort Bragg, has opened an office in Redwood City. He has transferred his membership from the Mendocino Society to the San Mateo County Society.

M. F. Desmond, Burlingame, and John N. Blood, Redwood City, both of whom have been away from practice because of illness, have recovered sufficiently to carry on their work.

James Raphael, formerly connected with the South San Francisco Hospital, has removed to Berkeley.

❧

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper Jr., M.D., secretary)—No meetings are being held through July and August, a vacation having been unanimously declared. Physicians of the city are busy enough finding new quarters, there being an almost universal desire to be "on the ground" and not in a big office building since the earthquake. The result so far is a considerable association of "groups" in bungalows, either new or reconstructed. These men are, however, careful to state that they are associated together only by "contiguity." So may be noted the association of Robinson, Isaac, Ullman, and Hotchkiss; of Schurmeier and Bagby; of Pierce, Freidell, Wells, Ryan, and Stevens; and of Brush, Luton Means, Soper, Varick, and Allen and Marian Williams.

Damage to the St. Francis Hospital was considerable, and the miraculous escape of everyone in the building is remarkable. At first their patients were cared for at the Cottage Hospital tent colony, but later the old St. Francis building was prepared for their use.

The General (County) Hospital was badly damaged, but here also no one was injured. Patients were moved out onto the lawn, while the main building, nurses' quarters, and superintendent's buildings are being reconstructed.

Practice during the first days of the quake was much disturbed, due to temporary lack of telephones, gas, electricity, and quarters. Various members of the Society did community service—those of the Reserve Corps especially, Lieutenant-Colonel Ullman and Major Means having the particular duty of issuing passes to the myriads of people wishing to enter the damaged zone, and Wilson and Henderson giving many first-aid treatments at the Red Cross headquarters.

The quick action of the gas and electric employes in shutting off supply immediately undoubtedly saved the city from conflagration. The telephone operators, with walls crumbling all around them, stuck to their desks and maintained connections as long as possible, while the long distance wires were the first to be re-connected, giving the outside world a chance to inquire about conditions.

"When the earthquake came," writes Amy Cryan, "the forty nurses of the Santa Barbara Cottage Hospital were at breakfast, and at once—without delaying for orders—each one went to the patients she had just been nursing, as promptly and simply and courageously as if it had been part of her routine training. These girls carried out the patients, many of whom were helpless and some of them were heavy men, and not till afterwards

did they realize how strained their backs and arms felt. They did not realize that they had acted heroically; they did not even know how all-important their courageous work was to prove, since it left them ready to deal with the patients who were rushed down from the St. Francis Hospital, which was wrecked."

"Bright as are the pages of the history of medicine, the record of the Santa Barbara Cottage Hospital has brightened these pages still further with its gallant record of devotion to duty. Characteristically, it is left to an outsider to record that historic week."

CHANGES IN MEMBERSHIP

New Members—Alameda County—Donald D. Lum, Alameda; Thomas O. Lake, Berkeley; Gordon W. Roberts, Oakland.

Kern County—Thomas L. Matlock, Wasco.

Los Angeles County—H. N. Krohn, Charles F. Sebastian, Joseph M. Klein, Bernard Aronchik, Oscar S. Essensen, Frederick D. Facey, Howard L. Hatfield, C. H. Hayton, J. C. Ross, Cora Smith King, John F. Van Paing, Allan M. Wilkinson, M. H. Newman, Harry J. Mayer, Los Angeles; Ralph Kirsch, Lamada Park; Erle B. Woodward, Monrovia.

San Diego County—John J. Shea, Anita M. Muhl, William C. Newton, Philip M. Harker, San Diego.

San Mateo County—Fred C. Smith, Palo Alto.

Deaths—Sanborn, Christopher Allen. Died at Redlands, July 18, 1925, age 70. Graduate of Bellevue Hospital Medical College, New York, 1882. Licensed in California in 1888. Doctor Sanborn was a member of the San Bernardino County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Sigwart, Joseph Frederick. Died at San Francisco, August 2, 1925, age 39. Graduate of the St. Louis University School of Medicine, 1912, and licensed in California the same year. Doctor Sigwart was a member of the Sacramento County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Allergic and Toxic Properties of Lens Protein—Of eighty-six patients tested by Sanford R. Gifford, Omaha (Journal A. M. A.), with lens protein, 12.6 per cent gave positive dermal reactions. Of those giving positive skin tests, six showed unusual post-operative ocular reactions, which may well be interpreted as due to their sensitization to lens protein. In a further case with a very severe reaction there seemed no doubt of this. It was found possible to sensitize animals by injections of lens protein, so that dissection produced an increased ocular reaction; but this occurred most often in animals treated so intensively as to be immunized to lens protein. In eight patients with negative skin tests, ocular reactions, apparently due to absorbing lens matter, occurred, indicating some toxic factor, not depending on anaphylaxis, in the lens matter itself. Normal lens matter showed toxicity when injected into the anterior chamber of the eyes of animals, but cataractous lens matter was apparently much more toxic, nine of fourteen animals showing more marked reactions from the cataractous lens, and none more marked from the normal lens. There is evidence that autolysis of the lens proteins occurs, with the production of leukomains and allied products, which may be toxic, and that the chemical differences between cataractous and normal lenses can explain the greater toxicity of cataractous lens matter. While endophthalmitis phaco-anaphylactica, in the sense of Verhoeff and Lemoine, undoubtedly does occur, a large number of reactions to lens substance cannot be explained as anaphylactic, and perhaps a majority of such reactions are due to the toxicity of lens matter itself. Hence, a better name for the whole group of reactions is that of Straub, "endophthalmitis phacogenetica."

Anaphylactic Shock and Failure of Desensitization After Administration of Pneumococcus Type 1 Serum—The case reported by M. A. Blankenhorn, Cleveland (Journal A. M. A.), presented three unusual phenomena: 1. The patient developed fatal septicemia after surviving lobar pneumonia terminating in crisis by the aid of antiserum. 2. He became extremely sensitive in nineteen days after serum treatment, but the sensitization was not discernable by skin test. 3. Desensitization failed.

SOLOMON AND THE NEWER MEDICINE

Solomon was a great king and a wise man—and a blasé one we may imagine because, as the champion wise cracker of his day, he pulled that one about there being nothing new under the sun.

Of course, one may excuse Solomon. One may excuse any man with his reputed number of lady friends and wives. According to the fundamentalists, woman was made from the bone of a man—and she's been a bone of contention ever since. But, the point of it all is that Solomon, reputed the wisest bird of his day, either before or after his run-in with Sheba—we forget which—opened his mouth and spilled something that really justified his reputation for wisdom more fully than even he perhaps imagined at the time.

Speaking of avocados—this brings us to the subject of recent modern medical research and the eternal subject of metabolism, which is, after all, but the study of that wonderful engine, the body, in which cholesterol, activated by the sun bath in the skin capillaries, carries its resultant quality to the cell to explode it into activity, and so make the engine run.

Looking at medicine from the attitude of a man in the bleachers observing a game, it appears now that the study of internal function—in other words, internal medicine—is the line along which medicine in the future must advance.

Surgery, after all (and with all respect to the brilliancy of its performance) is but a makeshift—a tacit confession that we know of nothing better—nothing more that can be done. Yet in a wide range of conditions surgery may presumably be avoided, if the understanding of the causation of the final condition is arrived at, and the defective metabolism leading to it be corrected in time.

Comes now parathyrin, as perhaps the latest metabolic advance. Parathyrin is an extract of the parathyroid glands. It has shown wonderful results in tetany, either of disease or of traumatic injury of the parathyroids. It may be expected to show equally good results in the body metabolism of lime—hence, in the treatment of, say, spasmophilia, putrefactive bowel conditions, the treatment of ulcerative processes of the digestive tract or of the integument—or any condition depending largely upon lime imbalance, just as we already know that the pituitary is so intimately involved in the process of growth, and the thyroid in the maintenance of normal basal metabolism, and the adrenals with blood pressure and a normal or abnormal circulatory tone, as well as a possible defensive function in infectious processes.

And this brings us back to our text and the truth of Solomon's world-weary observation. Because all these extracts are derived from animal

organs—desiccated or otherwise—and for untold generations the Chinese have been feeding the organs of animals to the afflicted individual to correct internal function. And there you are. Endocrinology isn't such new stuff after all. It's only a refinement of method rather than a new or radical thing.

And yet—and yet one wonders where it all may lead in the eventual history of medicine. More and more it appears that the question of immunity and infection hinges upon metabolism—functional balance more than any other thing. Infection, then, depends upon a condition or conditions tending to make the body of the most fit soil for the infecting growth, and these conditions, even to the point of tissue change wrought by trauma, are but changes in metabolic balance, with a resultant lowering of resistance to a danger point. Health or unhealth at this rate would seem to be but a matter of metabolic—or function—balance, depending upon a bodily chemistry properly maintained.

Hence, one wonders if in the future the internist will not perhaps be the one to solve the riddle of such a maintained balance which so long ago led the Chinese to employ an organotherapy different from ours in form, though not in any sense different in intent.

At least it seems that if medicine is to advance greatly, it must advance along this line. Should it do so, prophylaxis or early attack on disease will profit, and polypharmacy will decline. Today the effort to sterilize is in reality the treatment of a symptom rather than any other thing. Naturally, if an infecting agent can be destroyed, the infected tissue, unless too greatly damaged, may eventually regain a normal or nearly normal tone. But how much better could the condition have been prevented or aborted before any great damage was done. Today do we not in actuality pay too much attention to the infection and not enough to the metabolic tone? Do we not treat the infection too much *per se*, and leave the body, once the infection is destroyed if we do succeed in bringing about its destruction, to recover its damaged balance as best it may—much like a battered tin Lizzie limping home on two cylinders and a flat tire? Are we not actually putting the cart before the horse in this way many times? If infection means lowered metabolism or a metabolism deranged, then does it not mean a metabolism still deranged even after the infection has been abated by whatever agency we have employed? And in this direction does it not lie for internal medicine to accomplish marvelous things? Will we come to a day when bio-chemic changes can be recognized early enough to prevent disaster from occurring before rather than after the fact? I don't know and you don't know. But it is pleasant to theorize. And to us it seems that with the medical man it lies to show whether Solomon's classic dictum was right or wrong—at least as to medicine.

A YEAR AND A MONTH

It is now a year and a month since the president of the Utah Medical Association, in his official capacity, and, as we suspect, because we had already won a pair of nickel-plated spurs as a writer of fiction, and hence knew a little about stringing words

together, appointed us as the incumbent of Ye Editorial Chair for the state.

Since then, however, we have tried our "damndest," as the cowboy put it, to make the Utah section of the Journal something which the medical men of the state might care to read. And, quoting the cowboy again, "Angels can do no worse."

Now that another convention approaches, however, and we may be given our just deserts and cast into the ash-can in favor of one better able to carry on the work we have attempted, it seems timely to say a word in our own behalf. First, then, we have tried to make the Utah section as interesting as we could, and as complete in regard to medical news. We want to thank the secretaries of the various county societies who have co-operated, and we want to damn the secretaries who have not. The Utah section should be representative of the state. Merely because the editor happens to be a Salt Lake man is no reason why there should be a feeling, as has been intimated to him, that Salt Lake wants to hog the thing and would not print news from other parts of the state if it were submitted for use. And we want to say here and now that such a thought or statement is "all damp." What we would like above all things is a chance to get hold of all the information bearing on the medical activities from Cache County, south to Dixie. And we'll print it if we can get it to print. And we dare any secretary to send in his stuff and prove or disprove this statement. And we know who is going to be convinced. Yet, in the last year, only Box Elder and Weber have given us a chance to make good, and we've printed everything they sent. And we've thanked and do thank the secretaries of those societies for having given us the chance. And we wish the other societies would get up on the wagon and help drive, instead of passing us up.

This, however, is not a belch. Because, in spite of all our disappointments in support, we have enjoyed the work, and we feel and we hope the readers feel with us that we have done something to improve the Utah section inside the last year and a month.

We thank you.

Utah News Notes (reported by G. U. Giesy, associate editor)—News this month resembles the proverbial hen's teeth. Everybody is vacationing or going to vacation or has vacationed. The societies are not meeting. About all that is left is routine work, and that is something we can't report.

Drs. Root, Schulte, and Rich have returned from Europe, after a very enjoyable trip.

Dr. Sandberg of Salt Lake has left for an extended trip to Europe with his bride. During their absence they will visit England, France, Germany, and Austria. While in Europe Dr. Sandberg will do post-graduate work in Berlin and Vienna. The return home will be made by way of the Mediterranean countries, with a tour of Canada to round off the honeymoon.

The following physicians have been recently licensed to practice within the state:

Maurice Carver Melrose of Iowa, Vernon Scott Lilly of Ohio, James Albert Pederson of Washington, D. C.; Frank J. Lemon of Washington, and Thomas Francis Welsh of Nebraska. The new physicians admitted through examination are Robert E. Smylie of Price, T. M. Aldous of Springville, Leslie A. Smith of Logan, Leslie J. White of Salt Lake, Junio E. Rich of Ogden, Silas S. Smith of Salt Lake, and H. Asa Dewey of Bingham.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
 CLAUDE E. PIERSALL, M. D., Reno.....Secretary-Treasurer and Associate Editor for Nevada

TWENTY-SECOND ANNUAL MEETING

As we go to press, the Twenty-second Annual Session of the Nevada Medical Association is being held at Elko. The program, as given below, is a splendid one; and many of the papers, carefully edited and discussed, will appear during the year in CALIFORNIA AND WESTERN MEDICINE, as the official publication of the N. M. A.

The meeting is being held September 4, 5, and 6, so that members and guests may also take advantage of the Utah annual meeting and post-graduate week, at Salt Lake, September 7 to 12.

Officers and committees of the N. M. A. are as follows:

Officers—President, William M. Edwards, Yerington; First Vice-President, A. J. Hood, Elko; Second Vice-President, A. F. Adams, Reno; Secretary-Treasurer, C. E. Piersall, Reno. Trustees—W. A. Shaw, Elko; A. P. Lewis, Reno; George F. Pope, Winnemucca.

Council—S. K. Morrison, Reno; Hal L. Hewetson, Las Vegas; J. T. Reese, Yerington; William Howell, Gardnerville; F. M. West, Lovelock; A. L. Stadtherr, Reno; P. D. McLeod, Tonopah; William Brennan, Eureka; Charles E. Sweezy, Winnemucca; M. J. Rand, Ely; William Riley, Gold Hill.

COMMITTEES

Membership—B. Brown, A. C. Olmsted, C. C. Bullette. Judicial—M. A. Robison, A. J. Hood, R. A. Bowdle, A. R. Craig, Horace J. Brown.

Scientific Work and Program—V. A. Muller, J. C. Ferrell, A. Huffaker.

Necrology—Mary H. Fulstone, Donald Maclean.

Entertainment—C. E. Secor, W. A. Shaw, J. R. Eby.

Public Health and Education—Henry Albert, W. A. Shaw, M. R. Walker.

Delegate to A. M. A.—C. E. Piersall.

Alternate—William M. Edwards.

Military Affairs—The President, Vice-President, and Secretary.

PROGRAM

Friday, September 4, 1925

Elko General Hospital

Colonel L. M. Maus, Hot Springs, Ark.—Hydrotherapy at Hot Springs, also Medical Exhibit. Discussion by R. H. Richardson, P. K. Brown, and M. J. Rand.

J. F. Kerby, Salt Lake City, Utah—Anomalies, Diseases and Injuries of the Spine. Discussion by James Watkins and D. Maclean.

George L. Eaton, San Francisco, Calif.—One Hundred and Fifty Prostatectomies. Discussion by A. L. Stadtherr, V. A. Muller, and W. B. Coffee.

Edgar L. Gilcreest, San Francisco, Calif.—The Treatment of Fractures of the Elbow Joint and the Lower End of the Humerus. Discussion by A. R. DeCosta, A. J. Hood (Elko), and J. T. Watkins.

Henry Albert, Reno—The Prevention and Control of Infantile Paralysis. Discussion by John Tees, J. E. Worden, G. L. Belanger, Alex McIntyre, and G. L. Dempsey.

At the noon luncheon, Dr. Gilcreest will give an illustrated talk on Reminiscences of Sir William Osler.

William H. Brennan, Eureka—The Physician in Politics. Discussion by D. Maclean, George Servoss, A. C. Olmsted, and M. A. Robison.

W. H. Riley, Gold Hill—Problems of the Industrial Surgeons. Discussion by D. Maclean, James Watkins, and H. J. Brown.

Horace J. Brown, Reno—The Workings of the A. M. A. Discussion by M. A. Robison, A. R. Kilgore, and S. K. Morrison.

Philip King Brown, San Francisco, Calif.—The Medical and Surgical Treatment of Angina. Discussion by E. H. Falconer, T. W. Bath, C. E. Secor, and W. J. Van DenBerg.

Eric A. Larson, Woodland, Calif.—The Treatment of

Peptic Ulcer. Discussion by J. W. Gerow, G. R. McGee, and G. L. Eaton.

Saturday, September 5

Professor R. G. Foster, of Nevada Agriculture Extension Division, U. of N., Reno—Health Contests among 4'H. Clubs.

W. B. Coffee, San Francisco, Calif.—Discussion by R. A. Bowdle, M. B. Wesson, W. A. Shaw, and S. M. Sproat.

Miley B. Wesson, San Francisco, Calif.—Conservation vs. Radical Surgery for Traumatic Rupture of the Kidneys. Discussion by B. H. Caples, E. L. Gilcreest, and A. L. Stadtherr.

V. A. Muller, Reno—The Management of the Goiter Patient. Discussion by W. B. Coffee, R. P. Roantree, and H. L. Hewetson.

W. W. Washburn, San Francisco, Calif.—Intestinal Obstruction. Discussion by E. A. Larson, B. Brown, and C. W. West.

Maxmilian L. Herzig, Seattle, Wash.—A Study of Thoracoplasty in Unilateral Pulmonary Tuberculosis. Discussion by P. DeM. McLeod, A. P. Lewis, and D. G. Lynwalter.

T. W. Bath, Reno—Gonorrhea in Women, Pathology and Treatment. Discussion by A. B. Spaulding, G. W. Green, and A. L. Thompson.

A. B. Spaulding, San Francisco, Calif.—The Surgical Utility of the Pelvic Fascia in Cases of Cystocele, Rectocele, and Uterine Prolapse. Discussion by E. A. Larson, E. K. Smith, and H. W. Sawyer.

Albert Soiland, Los Angeles, Calif.—The Granuloniata, Hodgkin's Disease, Lympho-Sarcoma, and Leukemia. Discussion by A. R. Kilgore, W. N. Kingsbury, and J. F. Kerby.

The business session will be held in the Elko General Hospital, 8. p. m., Friday, September 4. Just following the business session will be moving pictures, showing pulmonary tuberculosis, presented by the Reno Radium-X-Ray Association.

Banquet at Lamoile Saturday evening.

Sunday, September 6, will be devoted to a fishing trip. Ladies cordially invited.

Arrangements are made for other entertainments. Announcement of details will be made at the first session.

Clinics will be held at the Elko General Hospital.

The Washoe County Medical Society, reports Henry Albert, secretary, met in regular session in a room of the Chamber of Commerce, August 11, President Vinton A. Muller presiding.

Business—The application for membership in the Society made by Carl H. Lehnert, having been approved by the Board of Censors, a motion was passed that the secretary be instructed to cast the unanimous vote of the Society for the election of Dr. Lehnert.

The secretary read communications from representatives of the Treasury Department of the Federal Government, in answer to the request of the Society to have the Federal Government discontinue the war tax imposed on physicians under the Harrison Narcotic Law; and also to permit certain professional expenses incurred in connection with medical meetings and post-graduate study deducted from the physician's income in the computation of the income tax. The replies in each case indicated an attitude on the part of the Federal Government that present rulings were justifiable.

L. G. Kassabian applied for membership in the Society. The application was referred to the Board of Censors.

Program—Drs. S. K. Morrison and R. H. Richardson gave very entertaining and instructive talks on "Observations and Impressions of Medical Activities Abroad." They recently returned from a visit to the medical centers of Canada, England, Ireland, and Scotland. The visit was made in company with about three hundred other physicians.

Attendance—Members: Adams, Albert, Bath, Brown, Caples, Da Costa, De Chene, Fuller, W. H. and A. J. Hood, Lewis, Morrison, Muller, Piersall, Richardson, Robinson, Robison, Tees, Thompson, Walker.

CORRESPONDENCE

POPE TRAVELOGUE

Tanganyika, June 23, 1925.

My dear Dr. Musgrave—Since writing you last, Africa has furnished quite a bit of amusement to our hunting party. A portion of this was the mix-up which Stewart Edward White and his two gun-bearers had with a leopard.

The dispatch news of this event has, of course, been in the daily papers—at least I walked thirty-four miles to the nearest human contact and started the message to Mrs. White.

You recall the episode, a common one in this country: White wounded a leopard with a bullet in the body, too far back to kill it outright. The beast entered the jungle, and in an attempt to rouse him from his retreat, the gun-bearer was attacked, the two rolling over in combat on the ground. White could not shoot, for fear of killing his man. A second gunboy ran up and was, in turn, borne to the ground by the fighting animal. White now had a chance to land a shot. The leopard left his second victim and sprang upon White, knocking the gun from his hands and bearing him to the earth.

White clutched the beast by the throat and threw his weight upon its chest until he choked it to death. He was bitten in the arms and shoulder and clawed in the face.

The second gun-bearer was bitten in the arm, and the first man was a mass of shredded flesh. His arms were deeply wounded by the leopard's fangs, his scalp was torn loose from his skull and lacerated to an extensive degree, but, worst of all, the animal caught the skull between his jaws and tried to crush it. One fang entered the orbit, ripping the eyelid to pieces, fracturing the outer bony structure and almost enucleating the eyeball. The wound extended deeply into the temporal fossa. The opposite fang grooved the calvarium as if a gouge had been driven over the bone.

The disfigurement was terrible!

White disinfected all these wounds as best he could with permanganate crystals.

By the time I arrived on the scene several hours later, they were laid out under a thorn tree, and a pretty mess of tatters and blood.

White insisted that I attend to Solomani, the gun boy, first. I dressed his wounds in saturated permanganate solution on gauze, after syringing them all to their depths with the same. Having treated all men alike, we made a crude stretcher for Solomani and carried him to camp, some four miles. He was in shock, of course. When I got him in camp I set out my surgical equipment, which was hardly adequate for wholesale injuries of this sort.

I gave Solomani chloroform and operated upon him at the same time, having no assistance but one intelligent tent boy, Hassani.

Out in the open, with a few boxes for tables and the simplest outfit in the world, we did the best we could for the poor fellow, cleaning his wounds, opening up pockets for drainage, repairing his ragged eyelid, and putting his optic back where it belonged. I was the only white man on deck—Young and Simson were in Nauobi, and the astonished natives stood around with China eyes, to see me cast one of their number into so deep a sleep that I could cut and sew without pain. We applied moist dressings and put him back on his straw couch in his little mud hut.

White's wounds healed nicely, and on the third day following, just to show his status, he went out and shot another lion—and, incidentally, broke open his shoulder wound.

The second gun boy, Kysuma, also recovered with a moderate amount of infection. But poor Solomani, when I removed his dressings next day, I found every scalp wound crawling with maggots, which I killed with a kerosene compress, and two or three days later every wound was running good, old trench pus, with bacteria of every known description, I assume.

For three weeks I've had a daily clinic, dressing wounds

that would satisfy a hyena for richness of odor and quantities of pus.

Dakin's solution would have been the thing to use, but unfortunately we are six weeks away from the nearest supplies. I syringed the deep wounds with a dilute iodine solution and kept the compresses moist with sheep dip, the only antiseptic that I had in quantity.

The eye has undergone a pan ophthalmitis, and I fear is a complete loss. Fragments of bone and bits of grass driven way back in the orbit came out with the flow of pus, and the eyeball will have to be enucleated soon, I fear.

The lacerated and punctured wounds made by the leopard's long canine teeth in the forearm are remarkable. There are half a dozen or more and extend completely through the muscles of the upper segment, but do not fracture either bone. They look a good deal like shrapnel injuries. Fortunately, no large nerves or blood vessels seem to be severed and the joint is not invaded, though the olecranon bursa was ripped open.

No anti-tetanic serum was used; we had none. Salvarsan has been employed in other cases of septicemia following lion bite, and the reports are good.

So this is Africa! Well, these predatory creatures know their business. We have met officially and taken the scalps of thirty-four lions and five leopards to date, and the score is in our favor so far. They have registered a dozen close misses and three hits; we have stung thirteen with our shafts, mortally wounding seven and killing the rest outright. The others we have had to use more persuasive arguments on, and they capitulated. Otherwise all is peace and quiet.

Yours as ever,
SAXTON POPE.

The new plant of the Abbott Laboratories, pictured below, is now nearly ready. Here the newest synthetic, medicinal chemicals are made in large quantities by improved processes, insuring purity and accuracy. Here also are extracted from the crude drugs the medicinal principles used largely throughout the pharmaceutical industry, as well as by the medical profession.

Larger quarters will be provided for the extensive research work now being carried on by a large staff of chemists, and new buildings are being provided for the manufacture of the well-known Abbott pharmaceutical specialties.

The administrative office of the Abbott Laboratories will be moved about October 1 of this year to the new plant. The postoffice address will be Waukegan, Illinois.

Every advertiser is a purchaser of character and circulation in certain proportions when he contracts for advertising space in any publication. Like the purchaser of the publication property, he must decide if he will base his estimate of its value to him on the volume of its circulation alone or upon its standing among its readers, which is a direct reflection of its character. Circulation is a product of salesmanship. Character, in a publication, is the issue of a union of high ideals with rigid standards of performance. Circulation alone can give no assurance of stability in the market it reaches, for readers may come and go, stay for a while and pass on, yet so long as salesmanship keeps renewal apace with mortality, volume remains unchanged. Character, however, is the guarantee of stability, for confidence in any publication is based on its character; and confidence begets continued loyalty, which in turn insures stability. And who can say that a stable market is less desirable than a fleeting one?—Reprinted from A. B. P. News.

Basic Facts About KLIM in Infant Feeding

KLIM is whole milk—pure and uniform—from which the water has been removed. In it the nutritive properties of fresh cow's milk are retained in highly assimilative form.

It is the basis for safe and simplified infant feeding and so closely conserves the flavor and the natural properties of milk that it is the ideal milk for the growing child.

Analysis of

KLIM

POWDERED WHOLE MILK

	Dry	Liquid *
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

White Enameled Ware

What rent do you pay for sterilizer space?

Have you a sterilizer in one corner, a work table in another, and a cabinet in still a third place—three pieces of necessary furniture taking valuable space?

For the crowded office, these are pertinent questions.

Owners of this CASTLE 426-S find that it requires about 50 per cent less space than its equivalent in separate parts and is more generous in conveniences. Everything is mobilized for quick use.

Send for literature.

*Error proof instrument tray.
Sterilizer cannot boil dry.
Instruments will not overheat.*

for Non-Sugar Diets

Famous S&W quality canned fruits, packed in *sterile water* or *natural juice*, instead of syrup.

Nutradiet canned fruits contain a minimum of carbohydrates. They contain less sugar than the fresh fruit itself because a portion of the natural sugar is thrown off into the water.

May be prescribed in cases calling for non-sugar diets. Write for chemical analysis of Nutradiet fruits. Also list of grocers having them for sale.

[Nutradiet salt-free vegetables include a variety of vegetables packed without salt or sugar.]

Wellsworth Professional Unit for Oculists

Here is the only complete refracting unit which is attached to the chair. It combines economy of space with convenience for the refractionist and comfort for the patient. It requires less space to house and operate than any other unit. The adjustable back, seat, headrest and arms give the patient utmost comfort.

The instrument support permits the use of each instrument independently. Each instrument swings before the patient in regular routine.

Equipped with scientifically precise Wellsworth-DeZeng diagnostic instruments, it is the most accurate and practical unit obtainable. The scientific appearance favorably impresses and increases your clientele.

TRUTH ABOUT MEDICINES New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Eli Lilly & Co.—Diphtheria Toxin-Antitoxin Mixture 0.1L plus; Typhoid Mixed Vaccine, Prophylactic and Therapeutic Schick Test, 50 test package.

Parke, Davis & Co.—Germicidal Discs of Potassio-Mercurio Iodide.—P. D. & Co.

Powers-Weightman-Rosengarten Co.—Bismosol; Bismosol Ampules, 1 cc.

Tuna Fish Protein Extract Diagnostic (P. D. & Co.)—A protein extract diagnostic—P. D. & Co. (New and Non-official Remedies, 1925, p. 289).—Parke, Davis & Co., Detroit.

Schick Test (Lilly) — Diphtheria Immunity Test (Schick Test) (New and Non-official Remedies, 1925, p. 50) is also marketed in packages of two vials, one containing diphtheria toxin sufficient for fifty tests, and the other vial containing the proper amount of diluent.—Eli Lilly & Co., Indianapolis.

Industrial Health Under Non-Medical Supervision —Emery T. Hayhurst, Columbus, Ohio (Jour. A. M. A.), summarizes his views on this topic as follows: For the public weal, industrial health simply requires sanitarians to take charge, both official and non-official, medical and non-medical, with local health departments supervising, and guided considerably by the experience of those industrial physicians and surgeons whose duties actually extend to hygiene and sanitation of working conditions in their respective plants.

Physicians & Surgeons Institute of PHYSIO-THERAPY

Announcing Summer Courses of Instruction in Physiotherapy

Physicians, graduates in Medicine only. Class A requirements. August 10 to October 10. Short, intensive, clinical courses.

Instruction will cover technique, indications and contra-indications for the use of each modality in the auxiliary treatment of disease and injury.

The course is adapted to each physician's individual needs in regard to the subject matter taken up, including the length of the course. For further particulars apply in writing.

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water.

Summer Diarrhea

Mellin's Food
Water (boiled, then cooled)

4 level tablespoonfuls
16 fluidounces

This formula provides a means of supplying the principal fuel utilized in the body for the production of heat and energy and furnishes immediately available nutrition well suited to protect the proteins of the body, to prevent rapid loss of weight, to resist the activity of putrefactive bacteria, and to favor a retention of fluids and salts in the body tissues.

While the condition of the baby will guide the physician in regard to the amount and intervals of feeding, the usual custom is to give one to three ounces every hour or two until the stools lessen in number and improve in character. The food mixture may then be gradually strengthened by substituting one ounce of skimmed milk for one ounce of water until the amount of skimmed milk is equal to the quantity of milk usually employed in normal conditions.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue
San Francisco, Calif.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

The Normal Diet. By W. D. Sansum, M. D. Published by C. V. Mosby Company. Price, \$1.50. For sale by advertisers in this issue of California and Western Medicine.

Doctor, this is the book you have been looking for to recommend to members of your clientele. It is brief (70 pages), accurate, and the subject of diet is presented most attractively.

Recovery Record. For use in tuberculosis. By Gerald B. Webb and Charles T. Ryder. Review copy by courtesy of the publisher, Paul Hoeber. Price, \$2. For sale by advertisers in California and Western Medicine.

This interesting little manual will be welcome to the physician, as well as to the patient who is taking "the cure." All the aspects of treatment in which the patient must co-operate are reviewed. The reasons for restrictions are clearly explained. The "false cure," first emphasized by Laennec, is mentioned, and "emphasis and reiteration that the treatment of tuberculosis calls for a thorough and prolonged rest" is dealt with at length. The many factors, including both the physical and mental aspects of the disease, are stressed, especially the need for properly graded mental occupation during convalescence, the accidents and obstacles, the record of disease, the technic of recovery, and the hygiene of recovery.

The chart sheets at the back are sufficient in number to last for two years. They are the usual temperature, pulse, and weight charts used by patients in a sanitarium. Each chart contains some well-adapted quotations. The cheerful philosophy and serenity which characterize the book make it a valuable adjunct in the care of the tuberculous patient.

Laws (Abstract) and Board Rulings Regulating the Practice of Medicine in the United States and Elsewhere.

Revised to May 1, 1925. Price, 60 cents. Copyright 1925 by the American Medical Association, 535 North Dearborn Street, Chicago.

This useful little book of 250 pages should be on the desk of every physician and every health worker of whatever kind in the whole United States. It contains a digest of the laws and board rulings of all states and most foreign countries; is exceedingly well done, with enough intelligent comment to give interested readers valuable information about the general conditions necessary to secure a license to practice medicine.

This is another of those useful services the A. M. A. is rendering to its members and to the public at large.

Choice of a Medical School. Reprinted from the Journal of the American Medical Association, with revisions and additions.

This pamphlet of some twenty-five pages will be exceedingly useful to young men and young women contemplating the study of medicine. It is part of the ever-growing splendid service that the A. M. A. is rendering, not only to physicians, but to the public as well.

Education in Roentgenology—Preston M. Hickey, Ann Arbor, Michigan (Journal A. M. A.), is of the opinion that roentgenology as a modern specialty is inadequately taught in a large percentage of the medical colleges in the United States. Roentgenology should be recognized as a separate department in all standard medical schools and should have a director of professorial rank. The teaching of roentgenology in medical colleges should be carefully correlated with the other branches, so that the students would receive proportionate and adequate instruction in this specialty. The Class A hospital should assist in the teaching of roentgenology by affording its interns the opportunity to become acquainted with the every-day applications of its principles. The training of the specialist in roentgenology should be one of the functions of a Class A hospital.

Epidemiologic Methods—Don M. Griswold, Iowa City (Journal A. M. A.), describes methods of procedure and the construction and use of chronologic charts, spot maps, case records, and special graphs.

St. Joseph's Hospital

Buena Vista and Park Hill Aves., San Francisco

Accredited by the American Medical Association, American College of Surgeons. Accredited School of Nursing. Open to all Members of the California Medical Association.

A limited general hospital of 200 beds, owned and operated by the Franciscan Sisters of the Sacred Heart. All classes of patients admitted except those suffering from communicable and mental diseases. This hospital was organized in 1889 and has been in continuous operation since that date. A modern annex was built in 1906. A further extensive building program is now under way.

Oculists or Optometrists—Which?—James M. Patton, Omaha (Journal A. M. A.), believes that the majority of optometrists are in the main making an honest effort, through preliminary training and the establishment of definite standards of ethics and proficiency, to render service to the public. However, during the last five or six years there has been a growing activity on the part of certain optometrists, some of whom hold official positions in state optometric organizations, which can be interpreted only as an attempt to restrict the rights of the regularly licensed oculist so far as the fitting and prescribing of glasses is concerned, even looking forward to the time when all oculists will be compelled by law to pass an examination before the board of optometry of the state in which he may be located. The status of optometry in each state is reviewed by Patton. He concludes by saying: Let us remember that there is an active group of influential optometrists who are perfectly willing to prevent by law all who are not registered optometrists from fitting glasses, and that active measures are contemplated to compel the oculist to pass their boards, before he can legally practice this phase of his profession. Let us be suspicious of bills regulating optometry containing ambiguous clauses, or those restricting the rights of manufacturing opticians who ordinarily serve the oculist. Let us remember that ours is a profession and not a trade. We cannot afford to face the charge of making a profit out of the glasses we prescribe, but we do have the right to protect our patients from the exorbitant prices and high pressure retail sales methods of the optometrists. We must be awake to the situation; and, while we may have no quarrel with the optometrist who limits himself strictly to his own field, at the same time, we owe it to our profession and to our patients to forestall any legislation which will limit the fitting of glasses to a single group.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

CALCREOSE

Intestinal Antisepsis

Attempts at intestinal antisepsis in the treatment of diseases of the intestinal tract that occur commonly during the hot summer months are considered important by many physicians. Creosote is regarded as an intestinal antiseptic of promise. Many physicians prescribe CALCREOSE for that purpose because it is a mixture of approximately equal parts of pure beechwood creosote and calcium oxid and can be taken for a long time without apparently causing any gastro-intestinal disturbance; nor do patients object to its long continued use. Samples of Tablets on Request.

The MALTBIE CHEMICAL COMPANY
Newark, New Jersey

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

Little Basin Ranch as a New Health Resort

The Little Basin Ranch, in the heart of the Santa Cruz Mountains, often spoken of as "Little Yosemite," and one of the most beautiful places in California, may be converted into a health resort, if plans already under way are carried out.

The ranch is within easy access of San Francisco and the Bay Region, and because of its ideal climate, it has been decided to establish a sanitarium, in the Little Basin itself, which will combine the features of a beautiful summer resort with that of a health resort.

The Little Basin Ranch consists of six hundred acres of wild mountain and valley, much of which is timbered and through which a beautiful mountain stream finds its way, supplied by numerous springs, located on the ranch. Ten acres of the valley bottom are under cultivation, planted to grapes, walnuts, and a variety of fruits and berries, while a portion of the ranch is stocked with thoroughbred Angora goats.

With this wonderful supply of mountain spring water, the fine elevation and scenery, there is no spot on the Pacific Coast more ideal for the development of a project such as the proposed resort.

Those interested in a project of this nature may secure information by addressing CALIFORNIA AND WESTERN MEDICINE, Box No. 950.

FOR RENT

OFFICE ROOMS

in the new

First National Bank Building East Bakersfield

Single rooms, \$20; 2-room suites, \$35 month.

Two exceedingly attractive corner suites, one of two rooms, the other of three rooms. Office rents include electric light, hot and cold running water, steam heat and janitor service.

All office rooms are connected by doorways, affording opportunity of having a number of adjoining rooms, if desired.

Exceptional parking space all around building.

Location, center of the "East Side" business district—a most promising site. Half of Bakersfield's population resides in this section. Only one physician and two dentists have offices here, while there are scores on other side of city. This is a wonderful opportunity for establishing a successful practice.

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game — the coon, fox, coyote — and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

A view of the Maternity and Children's Hospital, Toledo, Ohio.

A part of the "American" installation in the hospital laundry. The Photograph shows particularly two American Prim Presses.

And in Toledo....

THE modern hospitals of the country are turning almost unanimously toward operating their own laundries. For they have found that by so doing, it enables them to supervise their laundry service more closely, to maintain a smaller linen supply, and to have the work done more quickly.

One of the many representative hospitals maintaining its own laundry is the Maternity and Children's Hospital, Toledo, Ohio. Here an installation of "American" machinery handles all the laundry work with entire satisfaction.

As a progressive hospital superintendent, you, of course, are interested in the laundry department. And we invite you to confer with our corps of engineers concerning any question of laundry installation or management. We shall also be glad to put at your disposal figures on laundry operation that we have collected over a period of many years.

Full information about the Toledo and other representative "American" installations will be sent on request.

HANOVIA

*Pioneer in
Quartz Light
Therapy*

FOR THROAT AND ORAL INFECTIONS

Quartz Light is a widely accepted modality for the treating of throat and oral infections, such as Tubercular and non-specific Laryngitis, Tonsillar infections, Hyperesthetic Rhinitis, Bronchial Asthma, Hay Fever, Stomatitis, Gingivitis, Pyorrhea and post-operative conditions.

Such treatments are rendered particularly effective by the Wagner Prismatic and Ashland Universal quartz applicators, adapted to the KROMAYER LAMP — permitting the greatest concentration of ultra violet rays with the utmost convenience in handling.

The KROMAYER LAMP is especially and scientifically designed to meet those various conditions confronted by the physician in everyday practice. While, the entire quartz mercury anode type burner insures maximum intensity of rays, longer life and lower operating cost.

KROMAYER LAMP

*Special

Gentlemen:

Please send me, without obligation, special data and reprints upon the treatment of throat and oral infections with Quartz Light.

DR.

STREET ADDRESS CITY STATE

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

San Francisco

For Sale, Bargain. Notice to the Healing Profession

A first class convalescent home, well advertised and well patronized. High reputation. Can be converted easily, if desired, into a maternity hospital or some other medical utility. A four-story building, fine architecture, beautifully and centrally located in the heart of San Francisco, where property is daily rising in value. Just like new and with all modern built-in features. Plenty of closets, cedar chests, spacious corridors, fire escapes, with plenty of exits. Electric bells in all rooms, with speaking tubes and register. Dumb waiter, large kitchen with all facilities, garden front and rear, bay view from one side and panorama of San Francisco on the other. High and dry and full of sunshine. Office equipment, all sorts of tools, including gardening. Splendid heating and lighting system. 27 elegantly furnished rooms, some in mahogany and walls to match and hardwood floors, 3 sun porches, 4 bath rooms, 4 toilets, garage, barn, etc. 25 beds, all occupied and paying from \$300 to \$400 per week. Net profit to right party 50 per cent. I hold a building permit for more wards and roof garden, but am called East on important matters. If you ever dreamed of a gold mine here it is. A bargain at \$30,000. All I ask is \$25,000. \$8000 is a mortgage and \$17,000 must be in cash. 870 Fell street, Phone Hemlock 2220.

Teaching of Urology to Interns—William C. Quinby, Boston (Journal A. M. A.), is convinced that it is manifestly impossible to acquire proficiency in this branch of surgery during those relatively few months comprised in the usual hospital internship. It is very important, however, that a well-balanced surgical instruction should familiarize the intern with the outstanding features of our present knowledge concerning diseases of the urinary apparatus, so that on graduation he may see all types of disease in proper perspective. Should he then wish to devote his time intensively to this type of surgery, he will renew his hospital appointment as assistant resident, and later progress to the post of full resident.

*The Victor Two-Section Mobile
High Frequency Apparatus*

A Diathermy Machine of Major Calibre for Both Office Use and Treatment at the Bedside

Truly mobile. The apparatus proper (upper section) may be removed from the cabinet (lower section) and conveniently placed in the auto to facilitate treatment in the patient's home. In pneumonia cases especially is this feature appreciated

The physician who does only a moderate amount of reading of medical literature is aware of the present wide and rapidly increasing use of diathermy in medical practice.

For many years the Victor organization has studied this trend, during which one of the outstanding problems was to design an apparatus which would be of major calibre and at the same time so compact as to permit its being conveniently moved about, even to the patient's home when necessary.

Whatever may have been your past experience with high frequency apparatus of the portable type—most of which have served

only as mere introductions to the full possibilities of this form of therapy—bear in mind that the Victor Two-Section Mobile High Frequency Apparatus stands out as an engineering achievement that is destined to prove diathermy an important daily factor in the physician's armamentarium.

The machine is held down to compact size without sacrifice in the quality of currents delivered. In short, this Victor machine is not a toy—rather it incorporates the honest intent of its designers to place in the physician's hands an outfit of major calibre with which he may confidently anticipate the best therapeutic results.

If you would know of the far-reaching possibilities of high frequency therapy in your practice, write our Biophysical Research Publications Bureau for interesting and instructive literature

Mount Zion Hospital

AND

School of Nursing

2200 Post Street - - - - - San Francisco, California

A General Hospital of 170 beds, thoroughly equipped, all modern facilities. Free Clinic and Out-Patient Department. Accredited by American Medical Association and Standardized by American College of Surgeons. School of Nursing offers excellent opportunities to young women desirous of training for the nursing profession, and is accredited by the California State Board of Health.

Activities

Mount Zion Hospital Staff announces a weekly schedule of ward rounds, operative clinics, and special exercises, including a weekly staff conference to consider clinical problems of unusual interest. Visiting and out-of-town physicians are cordially invited to attend these exercises. Details of weekly programs may be obtained by telephoning West 7200 (Mount Zion Hospital), Franklin 1507 (S. F. County Medical Association), and Douglas 62 (California Medical Association). Following are the days on which the special exercises are held:
Monday 9:00 a. m.—Medical Ward Rounds. Samuel H. Hurwitz, M. D.
Tuesday 8:00 a. m.—Weekly Staff Conference.

Tuesday 9:00 a. m.—Urologic and Cystoscopic Examinations. Louis Clive Jacobs, M. D.
Wednesday 8:30 a. m.—Operations. Charles G. Levison, M. D., and Harold Brunn, M. D.
Thursday 8:30 a. m.—Eye, Nose and Throat Operations. Aaron Green, M. D., and Herbert Cohn, M. D.
Thursday 9:00 a. m.—Medical Ward Rounds. Emilo Jellinek, M. D.
Friday 8:30 a. m.—Clinical X-Ray Conference. Lloyd Bryan, M. D.
Friday 9:00 a. m.—Pediatrics Rounds. E. Chas. Fleischner, M. D., and Ralph Kuhns, M. D.
Friday 9:30 a. m.—Prenatal Clinic. Louis I. Breitstein, M. D.

To Our Customers

We maintain fully equipped commercial and research laboratories with facilities for all classes of analytical determinations. These additions to our plants have made it possible to conduct routine quantitative tests on all of our products, thus insuring you against fatalities due to hap-hazard production.

In addition to medical gases we also manufacture a full line of intravenous and intramuscular medications and are prepared to make up special formulas.

We solicit your co-operation in the ethical advancement of intravenous medications as well as anesthesia.

Announcing the Fourth Annual
Physiotherapeutic Convention

ARRANGEMENTS have been perfected for a really elaborate Physiotherapeutic Convention to be held at the

DRAKE
HOTEL

CHICAGO

October
12-16

1925

There will be lectures, clinics and demonstrations, all in charge of well-known physicians and surgeons. For purposes of demonstration, carefully prepared papier-mache or wax figures and models will be used, and in some instances live models will be employed for this purpose.

List of Speakers

- MILES J. BREUER, M.D.
Lincoln, Neb.
W. B. CHAPMAN, M.D.
Carthage, Mo.
M. H. COTTLE, M.D.
Chicago, Ill.

Hospital and Surgical Supplies — Wholesale and Retail

The most compact and complete X-Ray machine in existence—

If you have wanted an X-Ray unit—but haven't bought one because you didn't have the space for it—

Or because you felt an X-Ray unit must necessarily be cumbersome, complicated and intricate—

Or because you felt you couldn't afford to invest three or four thousand dollars in an X-Ray unit—

Send the coupon below, and we will mail you without cost or the slightest obligation our illustrated twenty-four page brochure, showing and describing the Rieber Fluoroscopic and Radiographic Unit.

The Rieber Unit is a unit. It stands 6 feet 8 inches high, is twenty-eight inches wide, and fits in any 3 by 6 foot floor space.

Tube, transformer, tilting table, fluoroscopic screen, radiographic feature are all included as a part of this Rieber X-Ray Unit.

Complete and positive control by one hand and foot, with the unit in any position.

The Rieber X-Ray Unit marks a revolutionary step forward in the construction of X-Ray apparatus—and the extremely low price of the Rieber Unit together with the easy terms on which it is sold puts it within reach of even the most modest income.

So that you may see and judge this exceptional device for yourself, mail the coupon below to us today.

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the method of presenting their subjects. It is believed that the author's presentation determines to no small degree the value of his conclusions.

Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented as little disturbed as possible by the editors.

However, the right to reduce or reject any article is always reserved.

Fruits for Non Sugar Patients

Fruits may now be prescribed for non-sugar diets, even when fresh fruits are not available.

Nutradiet canned fruits are the best quality fruits—the famous S & W standard of quality—packed *without* syrup.

Instead of sugar, Nutradiet fruits are canned in sterile water or natural juice. And a part of the natural sugar passes into the water after canning, leaving Nutradiet fruits with even less sugar than the fresh fruit.

Chemical analyses of Nutradiet fruits will be sent gladly on request. Also list of grocers where Nutradiet fruits may be purchased.

[[Nutradiet salt-free vegetables]]
are packed without salt or sugar.

Superior Products

Neo-Arsphenamine
DERMATOLOGICAL RESEARCH LABS.

GUARANTEE

EVERY batch of Neoarsphenamine, D. R. L., now made is guaranteed to have met a test for toleration almost 75% above governmental requirements.

Here is uniformity as remarkable as it is unprecedented.

In therapeutic results this unusual product compares favorably with Arsphenamine.

Sulpharsphenamine

THE Dermatological Research Laboratories were the first in America to manufacture Sulpharsphenamine, as well as Arsphenamine and Neoarsphenamine. This product is of a quality that justly entitles it to be listed with the D.R.L. line of superior anti-siphilitic drugs.

Potassium Bismuth Tartrate
With **Butyn**

PURITY of compound, high bismuth content and better absorption and elimination, coupled with practically complete freedom from pain characterize the D.R.L. product.

Preferable to mercury in most cases with greater spirocheticidal power and lower toxicity.

Insist upon D.R.L. products from your dealer.

ERGOT ASEPTIC

A DEPENDABLE UTERINE HEMOSTATIC.
TWICE THE STRENGTH OF THE U. S. P. FLUID EXTRACT.
SUITABLE FOR HYPODERMIC INJECTION.

MANY physicians depend on Ergot Aseptic because they can get prompt action with it and the full therapeutic effect of ergot. As it is relatively non-irritating and easily absorbable, it lends itself to hypodermic administration, preferably by intramuscular injection. Ergot Aseptic can be depended on in postpartum hemorrhage because of its powerful effect upon the uterus. It is of value in metrorrhagia and menorrhagia as well as in subinvolution of the uterus, and can be administered to advantage in labor after the delivery of the placenta.

In semiparetic conditions following abdominal operations it may be used to induce intestinal peristalsis. Osborne believes that when ergot is given with morphine it prolongs the sedative action of the narcotic and enables the physician to prescribe smaller doses effectively. It may be used in delirium tremens for its tonic effect on the circulation and its sedative action on the nervous system.

Ergot Aseptic has been recommended in cases of cerebral edema and stupor, with low blood pressure, and in acute collapse from broken compensation in valvular lesions of the heart accompanied by cold clammy skin, blue lips, and acute edema of the lungs.

Ergot Aseptic is a sterile aqueous solution of the active principles of ergot, containing a minimum of the therapeutically inert substances that are present in the fluid extract. It is physiologically standardized on young single-comb white Leghorn cocks by the method devised many years ago by Dr. E. M. Houghton, director of our medical research and biological laboratories.

Ergot Aseptic is supplied in ampoules only, each ampoule containing 1 cc, and the marketed packages contain three and six ampoules respectively.

Our booklet on Ergot Aseptic will be sent to any physician on request.

INSULIN · LILLY

TWO NAMES ALWAYS ASSOCIATED

In the minds of diabetic specialists in the United States, the name Insulin is very closely associated with the name Lilly.

In May, 1922, The Lilly Research Laboratories began co-operating with The Insulin Committee of the University of Toronto in the development of a process for the manufacture on a large scale of a pure, stable, uniform, high-grade preparation of Insulin. Within a few months several thousands of the clinicians in this country were receiving from the Lilly Laboratories ample supplies of Insulin for experimental work.

ILETIN (INSULIN, LILLY)

Iletin (Insulin, Lilly) was the first preparation of Insulin commercially available in the United States.

The name Lilly on pharmaceutical and biological preparations inspires confidence because for nearly fifty years it has stood for scientific products, ethically advertised and economically distributed.

Iletin (Insulin, Lilly) is supplied in 5 c.c. and 10 c.c. ampoule vials, U-10, U-20 and U-40.

All Lilly Products are distributed through the drug trade

Fecal Consistency

DESHELL STARCHLESS AGAR FLAKES

So much interest has been created in the superior American made Agar used in PETROLAGAR (Deshell) that we have decided to place it on the market as DESHELL STARCHLESS AGAR FLAKES, for the physician who, in certain cases, may wish to prescribe agar.

DESHELL STARCHLESS AGAR FLAKES are produced in a modern American factory on the California coast.

They are free from impurities, sterilized, free from starch—which affords at least 25 per cent. additional bulk.

DESHELL STARCHLESS AGAR FLAKES are unusually palatable.

They can be obtained on prescription from any pharmacy.

There is no questioning the fact that constipation may be cured in practically every individual by adherence to the principle of acquiring the proper fecal consistency from diet, and by the process of teaching the bowel to move at a certain time.

Herein lies the fundamental value of PETROL-AGAR (Deshell), for, without instigating the cathartic habit, and free from any possible harm, it gives to the stool the desired bulk, lubrication, and ease of passage.

PETROLAGAR (Deshell) greatly shortens the period of education of the bowel. It is so palatable that there is no objection on the part of the patient to taking it. The possibility of leakage is diminished, and it does not establish the cathartic habit.

The agar now being used in PETROLAGAR (Deshell) is an American made agar—a superior product, free from starch, which affords at least 25 per cent additional bulk.

PETROLAGAR (Deshell) has been accepted for New and Non-official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

PETROLAGAR (Deshell) is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

Beriberi From a Diet of Raw Starch—For six years the patient of E. J. Kepler, Philadelphia (Journal A. M. A.), had eaten raw starch. In August, 1918, she had a miscarriage followed by severe vaginal bleeding. One of her friends recommended raw starch as a therapeutic measure. Acting on this advice and later influenced by a superstition among negroes that raw starch has cosmetic value and tends to make the skin white, she gradually acquired a fondness for this type of food, and would eat it from the box, piece by piece, as one would eat candy. At the end of two years this habit had increased to such an extent that she was consuming one of the popular brands of gloss starch in amounts ranging from one to two pounds (0.5 to 0.9 kg.) daily—approximately from 1600 to 3200 calories. Her husband ate only one of his daily meals at home, and rather than cook for herself, she obtained most of her nourishment from the uncooked starch. She practically subsisted on laundry starch, which, so far as its vitamin content is concerned, is the equivalent of decorticated rice. No other peculiarities or excesses in her habits could be discovered. In spite of her starch diet from August, 1921, she remained in fairly good health until May, 1924, when she began to notice unusual sensations in her hands and feet. She felt as though pins and needles were being stuck in her extremities and that insects were creeping up and down the legs. By September 1, there was marked edema of the feet, pronounced dyspnea on exertion, and sufficient loss of power in the legs, so that walking became very difficult. On admission, a diagnosis of acute nephritis and multiple neuritis was made. After about ten days, a diagnosis of beriberi was made. The diet was then modified and autolyzed yeast given. Marked improvement followed. At present the patient is able to walk and is doing her own housework.

Bankers Realize the Importance of Malpractice Insurance

Professional protection is looked upon as a sound business investment by sound business men. The necessity of complete protection is best emphasized in the following letter:

"Medical Protective Co.,
Fort Wayne, Indiana.

Gentlemen:

Within this month, I have purchased a piece of real estate. In trying to make a loan on the property, there appears in the legal papers the fact that I have two damage suits pending against me.

In spite of the fact that I have assured the bank that I carry insurance in your company to protect me in such matters, they have requested that I have you write them a letter stating that I am insured in your corporation. May I request of you that you write such a letter at once, so that I can get this matter closed before the first of September, for by so doing the suits now pending will be no lien on this piece of property.

Thanking you in advance for your many services to me, I am

Very truly yours,"

The Medical Protective Contract is a guarantor of your financial stability in so far as a malpractice action is concerned. Twenty-six years in serving the profession with an experience of handling more than 19,000 claims and suits.

Your Service is more than a License—

Our Service is more than a Contract.

MARY'S HELP HOSPITAL

145 Guerrero Street, San Francisco
Accredited for Intern Training by the American Medical Association.
Accredited School of Nursing.
Open to All Members of the California Medical Association.
Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

My sales of medical books during the past month reached the high-water mark. I am in a position to know that they far exceeded the sales of any individual or firm on the Pacific Coast for the same length of time, on books on medicine and allied subjects. My thanks are due to the medical profession for the wonderful way in which they have rallied to my support. It proves that which I have always contended: to sell medical books one must know something about the contents of the volumes sold.

Mount Zion Hospital

AND

School of Nursing

2200 Post Street - - - - - San Francisco, California

A General Hospital of 170 beds, thoroughly equipped, all modern facilities. Free Clinic and Out-Patient Department. Accredited by American Medical Association and Standardized by American College of Surgeons. School of Nursing offers excellent opportunities to young women desirous of training for the nursing profession, and is accredited by the California State Board of Health.

Activities

Mount Zion Hospital Staff announces a weekly schedule of ward rounds, operative clinics, and special exercises, including a weekly staff conference to consider clinical problems of unusual interest. Visiting and out-of-town physicians are cordially invited to attend these exercises. Details of weekly programs may be obtained by telephoning West 7200 (Mount Zion Hospital), Franklin 1507 (S. F. County Medical Association), and Douglas 62 (California Medical Association). Following are the days on which the special exercises are held:

Monday 9:00 a. m.—Medical Ward Rounds. Samuel H. Hurwitz, M. D.

Tuesday 8:00 a. m.—Weekly Staff Conference.

Tuesday 9:00 a. m.—Urologic and Cystoscopic Examinations. Louis Clive Jacobs, M. D.

Wednesday 8:30 a. m.—Operations. Charles G. Levison, M. D., and Harold Brunn, M. D.

Thursday 8:30 a. m.—Eye, Nose and Throat Operations. Aaron Green, M. D., and Herbert Cohn, M. D.

Thursday 9:00 a. m.—Medical Ward Rounds. Emil O. Jellinek, M. D.

Friday 8:30 a. m.—Clinical X-Ray Conference. Lloyd Bryan, M. D.

Friday 9:00 a. m.—Pediatrics Rounds. E. Chas. Fleischner, M. D. and Jos. Sampson, M. D.

Friday 9:30 a. m.—Prenatal Clinic. Louis I. Breitstein, M. D.

How Can I Reduce the Cost of My Linen Supply?

A question in which **you** as well as every hospital superintendent is vitally interested.

And the answer is — *an adequate laundry*. Modern equipment, washers, extractors, ironers, etc., is capable of producing volume without the sacrifice of quality.

We ask the privilege of consulting with you so that we can endeavor to make your laundry department an efficient, capable and a satisfactory one to you.

It is our belief that this survey on our part, which obligates you in no way, will benefit you to such an extent that, in many cases at least, the improvements suggested will be self-sustaining.

With a corps of representatives covering the entire United States, it is an easy matter for you to promptly obtain their assistance in your laundry problems. Just drop a line to our nearest office.

DISEASES OF THE EYE, EAR, NOSE AND THROAT
GIANT MAGNET, OESOPHAGOSCOPY, BRONCHOSCOPY

Urologic Problems of the General Practitioner, Surgeon, and Internist—Robert V. Day, Los Angeles (Journal A. M. A.), discusses kidney function, hematuria and pyuria, renal tuberculosis, renal maladies of the clinically obscure abdominal type, catheter cystitis and latent prostatism in relation to general surgery. Speaking of the latter, he says: "A surgeon about to perform a serious operation on any patient should know that his patient is physically sound or, if not, know the nature and extent of all abnormalities present. In any male patient of the prostatic age (50 years old or more), particularly if the operation be for hernia or hemorrhoids acquired in the last few years, the catheter should be employed to ascertain whether or not there is residual urine. If the residual urine is considerable, kidney functional tests and preliminary drainage by an indwelling catheter should precede any elective operation for the same length of time one would take to prepare the same patient for prostatectomy. In the event of an emergency operation, an

indwelling catheter or regular intermittent catheterization should be employed. Prostatism, mis-called prostatic hypertrophy, is an adenomatous or sclerotic condition of the prostate, causing obstruction in some degree to the outflow of urine through the urethra. Hypertrophy of the lateral lobes or definite carcinoma may readily be felt by a finger in the rectum; but this procedure cannot be expected to disclose any evidence of middle lobe hypertrophy alone or of contracture or bar. The urine may be quite normal. A patient with clear urine is just as likely—sometimes more so—to have a severe infection with a stormy convalescence following a surgical operation (perhaps a fatality), as a patient with infected urine. In the presence of residual urine, cystoscopy is usually necessary to discover the precise nature of the obstruction. One should always be on the lookout for tabes or other disease of the central nervous system before diagnosing prostatism. However, they may co-exist."

The Ovarian Follicular Hormone—A determination of the amount of active substance extracted from different human genital tissues is made by Edgar Allen, Columbia, Missouri, J. P. Pratt, Detroit, and E. A. Doisy, St. Louis (Journal A. M. A.). This is measured in rat units by means of a decisive anatomic and physiologic reaction of the genital tract of the spayed rat to injected lipoid extracts. The follicular hormone is present in greater concentration in large ovarian follicles of women than in those of pigs. In pigs and cows, the secretion of this hormone ceases or wanes rapidly following ovulation; in women it is continued after ovulation by the corpus luteum for a considerable period. It seems possible that this may prove to be one of the principal determining factors in the difference between the estrous cycle of lower mammals and the menstrual cycle of primates. Extracts have been made of placentas from women and cows which give the same growth reaction in test animals as does the ovarian follicular hormone. The human corpus

of the first and third months of pregnancy contains some active substance, but the placenta contains much larger quantities. The evidence presented indicates that the corpus can be excised as early as twenty days following the last menstruation without interfering with normal gestation; consequently, this endocrine function of the corpus in woman during this time does not seem a necessary one. Two possibilities present themselves to explain placental endocrine function: Either (1) the hormone extracted from the placenta is elaborated there, or (2) it is retained there after being formed in the ovarian follicles or (in woman) in the corpus luteum. Further experimental evidence is necessary to settle this point.

The reader interest is the quality phase of a publication's circulation—because it means the percentage of audience to the total number of those for whom seats have been paid for by you.—Standard Rate and Data Service.

What an Eminent Physician says

about Gelatine in Milk for Infant Feeding

DR. JOSEPH LEIDY, of Philadelphia, says: "The combination of Gelatine and milk in infant feeding was long used by my father and the late Dr. W. Pepper. I have continued to use it during the past thirty years, and am of the opinion that it gives results when many other combinations fail." (*Quoted by permission.*)

Thomas B. Downey, Ph. D., Fellow of Mellon Institute, Pittsburgh, has, by standard feeding test, determined that the addition of pure, plain unflavored Gelatine increases the nourishment obtainable from the milk by about 23%.

The approved method of combining Gelatine with milk is as follows:

Soak, for ten minutes, one level tablespoonful of pure, unflavored, unsweetened Gelatine in one-half cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until Gelatine is fully dissolved; add this dissolved Gelatine to the quart of cold milk or regular formula.

Physicians are cautioned to prescribe only pure, unflavored and unsweetened Gelatine—the purest form of which is *Knox Sparkling Gelatine*—highest quality for health—produced by the most scientific methods, and under constant bacteriological and chemical laboratory control. It contains no artificial flavoring—no sweetening.

FREE

To Physicians and Hospitals

The Physician's reference book of nutritional diets with recipes will be sent free to physicians or hospitals, upon request, if they will address the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

In addition to the family size packages of "Plain Sparkling" and "Sparkling Acidulated" (which latter contains a special envelope lemon flavoring,) Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use.

KNOX

SPARKLING GELATINE

"The Highest Quality for Health"

Free from harmful acidity, artificial coloring, and synthetic flavoring.

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

Static Peritonitis in the Malnourished Infant—John A. Foote, Washington, D. C. (Journal A. M. A.), states that premature, toxic and typically athreptic infants display symptoms of peritoneal injury in a manner that may be termed static. One of his patients showed infection through the umbilical vein. In intussusception in the athreptic infant, pain, tumor, and vomiting may be seen only late in the disease, and diagnosis may be difficult. Even slight distention, not reducible by enemas, in emaciated infants, should be a contra-indication for intraperitoneal instillation of salt solution or blood. A gain of weight after this procedure in desperate ill athreptic infants means a non-absorbing peritoneum. Usually, by the time it is possible to establish the diagnosis with certainty, treatment is unavailing. Hence the need for prophylaxis of athrepsia by breast-milk feeding and care as to the hygiene of the infant in the first week of life. The use of pituitary extract to promote peristalsis in young infants is fraught with danger, since it readily produces intussusception.

The Robertson Therapeutic Lamp

An exceptionally high grade piece of apparatus embodying all the qualities found in the most expensive types. Easily adjustable in every desirable position owing to the balanced type of stand.

\$95.00

Complete with 1000 or 1500 watt clear or Therapeutic blue bulb and protective screen.

Also made in the Wall Bracket and Ceiling Suspension Types.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

REMARKS ON THE PRACTICAL TREATMENT OF DIABETES

By FREDERICK M. ALLEN, M. D., *Morriston, New Jersey*
(*Delivered before the San Diego Medical Society, November 18, 1924*)

DOCTOR ALLEN'S method of handling the subject of diabetes, by refuting many of the erroneous views that creep into the discussion of any new subject is particularly pertinent. Following promptly in the wake of any scientific discovery is a stimulated crop of all kinds of pseudo-scientific views bearing more or less closely upon the subject; and even we physicians are not above espousing them for a time. A direct negation, given by an authority we recognize, to the more plausible of these errors clears our vision and strengthens our practice wonderfully.—EDITOR.

I SHALL speak informally on the subject of the practical treatment of diabetes.

Many advances have been made in this subject, as you all know, and as in most subjects, many fads come and go. Sufficient time has now elapsed, I believe, for us to judge some of the recent movements in this subject, and I shall speak rather frankly and freely of my own notion of these movements. You are in no way obligated to believe what you hear.

In 1914 I set up certain innovations in diabetes in the form of a treatment based on something new in diet, namely, the limitation, not only of carbohydrate, but of total calories, the idea being that the tolerance is governed not only by the carbohydrate, but by the fat intake and body weight. In criticizing some of the ideas that have come up since that time, I am not attacking other individuals in expressing my opinion freely, but

rather defending my position against their attacks, and the question as to who is right will simply have to be decided by experimental evidence.

The treatment of diabetes is today practically twofold: by diet and by insulin. I shall consider the subject under these two heads, and shall begin under each heading by stating certain things which, in my opinion, are not true.

DIET TREATMENT

First of all, it is not true that insulin diminishes the need for accuracy of diet. Diet is just as live a question as it ever was, if not more so. Accuracy of diet is needed as much as ever, if not more, because formerly there was greater leeway in treating diabetes on lax diets; now if a diabetic takes insulin he is almost compelled to have a weighed diet. For that reason many physicians who never studied diets before are studying them now in order to treat diabetes intelligently with or without insulin. A very striking suggestion in that connection has been put forth by Gray, who, in a recent paper, raises the question: "Is insulin more important to the diabetic than food scales?" The point brought out is that, from a practical standpoint, food scales may be considered more important than this wonderful discovery, because most diabetics do not, after all, need insulin, but they all need diet, and those who do need insulin cannot be treated satisfactorily with insulin unless they have accurate diet. That is one way of expressing the importance of diet in diabetes. Now we still have deaths in patients treated with insulin. We still have deaths from old-fashioned diabetes, because those patients do not follow diet, and any idea that one can use insulin successfully simply by planning the dosage of insulin and disregarding everything else is contrary to fact. Diet, then, maintains its full importance.

Second. It is not true that any form of diet can take the place of undernutrition. There are various forms of reduced diet, the strictest of all being total fasting. The more you undernourish the patient the more you raise his tolerance. To feed him with the number of calories he is burning is not equivalent to fasting; that can be shown experimentally.

Third. It is not true that the respiratory metabolism can furnish a guide to the diet. Perhaps such remarks may unfavorably impress persons who do respiratory metabolism. I appreciate their work very highly and its importance for theoretical and practical purposes, but tonight I am speaking of a practical subject to practitioners. A large proportion of writers on this subject now speak of taking the basal metabolism and figuring the basal diet of the patient, and then building up a diet from that, giving him first the basal requirement. This may be very interesting if you are doing research work on the subject,

or perhaps if you have a new machine and like to play with it or to impress patients. But for actual practical benefit I see no advantage in taking observations of the respiratory metabolism. It does not guide one in the treatment, and it does not tell how many calories the patient needs. Whatever his basal metabolism is we must guess at his active metabolism, and it is just as easy to guess at the whole thing in the first place.

Fourth. Another point bearing closely upon this whole subject is the question of protein. It is not true that protein has any specific injurious action on diabetes. A number of older writers have argued that it has some influence as a special toxic food injuring the pancreas somehow or other. More recent writers have speculated that it may be injurious through its specific dynamic action, raising the metabolism, and that for this reason protein should be especially restricted. The only answer is that it is not true in actual practice. If you think otherwise, try it. Protein makes somewhat less tendency to glycosuria than the equivalent in preformed carbohydrate. If there were any special toxic action in protein, or if it especially influenced the tolerance through its raising of the total metabolism, it would create more of a demand for insulin than carbohydrate. The contrary is true. Carbohydrate creates more of a demand for insulin than its equivalent in the form of protein. Therefore, protein is not to be particularly dreaded in diabetes.

Fifth. The total calories of the diet cannot be ignored. This means in particular that fat cannot be ignored. The tolerance of the diet cannot be figured solely in terms of carbohydrate, assuming that all diets are the same if they contain equal glucose values in the form of carbohydrate as such, or protein, counting it as 60 per cent carbohydrate, or with allowance for any supposed carbohydrate value of fat. You cannot figure diabetic diets as equivalent on that basis, but must consider also their total caloric value. This principle is largely ignored in recent writings on diabetes, but is just as valid as ever.

Sixth. As a continuation of this idea, the high fat diets, so-called, which have been the most recent of the diabetic fads, and which are very extensively used today, in my opinion do not represent any valuable new step in the treatment of diabetes. They are practically a reversion to the old treatment with low carbohydrate and protein and high fat. They are a negation of the principle of the influence of total calories. The basic principle of the high fat diets is that carbohydrate is all that counts; that if we restrict the carbohydrate enough, and also restrict protein, the more calories we give in fat or perhaps alcohol the better. That is untrue. I have published the proof, and some others have also published confirmations. Until these experiments are overthrown the principle of total calories cannot be ignored. As a matter of fact, Newburgh and Marsh, whose names are associated with high fat diets, have not ignored this principle in actual practice. If one will look up their papers he will find that, although their cases on the average are mild, the total calories in their diets are not high. Men like Petrén in Europe have used actually high fat diets, running these diets as high as possible, often

above 3000 calories. But Newburgh and Marsh have done better. After an initial undernutrition with about 900 calories, they have limited their milder cases to about 2400 calories. Also, if you look up their original papers, you will find that their severe cases have received final diets only as high as 1500 calories. In other words, their diets were on the whole not higher in total calories than the diets of Joslin, myself or others for similar cases. They were not able to take thin diabetics and make them fat; nobody ever succeeded in doing that until insulin came. The reason is that the emaciated patient suffering with severe diabetes cannot assimilate high calories in any form.

Seventh. It is not true that the practitioner need go to the trouble of calculating ratios of the ketogenic and anti-ketogenic substances in the diet. That is again one of the fads that have complicated diet unnecessarily. In the first place, if we give a patient any ordinary combination of foodstuffs we are likely to use, we shall find that we have nothing to fear from acidosis provided glycosuria is kept absent. Newburgh and Marsh are perfectly correct in that principle, which is not new. If we keep a patient sugar-free we can give him huge quantities of fat in proportion to carbohydrate and protein, and not get serious acidosis. Wilder has published recently some very narrow ratios of carbohydrate and fat in the diet, allowing the patient to show some ketosis and finding that no apparent harm was done. It need not injure the patient if he does show a little acetone in the urine. It is extremely important theoretically to know what combinations of materials make acetone in the body and how and why ketosis arises. But even from a theoretical standpoint it is hard to tell where ketosis begins, and whether we should be guided by the first bare trace of acetone or only by a large increase. Practically no two authors agree as to the amount of ketogenic and anti-ketogenic materials a diet should contain. On the practical side I would say that we are interested only in making the patient safe and evidently various ratios are safe, but the main point is that they all fall within any diet we are likely to choose. Some people prefer higher fat, some lower fat, some higher carbohydrate and some lower, but I do not know anybody who can make any palatable combination of foods that would produce any serious acidosis in a patient who is sugar-free. Therefore, physicians need not worry too much about the scientific phrases.

Eighth. It is not true that there is any valid ratio of tolerance for different foods on the basis of their glucose value. It has been argued that in figuring the diet we must count the glucose available as 100 per cent for the carbohydrate, at 56 or 60 per cent for the protein, and at 10 per cent for the fat; and that thus diets can be planned which will prevent acidosis and at the same time supply high fat and high calories. The purpose of these calculations is to give the patient as many calories as possible. High caloric diets are what these authors have aimed at; their fundamental principle has been that only glucose need be considered, and that if you exchange other foods for fat you can give more calories in the form of fat, and therefore a higher fat diet is better. That is where the mistake lies. It is

not true that you can exchange 10 grams of carbohydrate for 100 grams of fat and have it mean the same to the patient. If you do that you are subtracting 40 calories and adding (with your 100 grams of fat) 900 calories; but they are not the same. If you could do this you could soon run up to a diet of 4000 calories, in return for taking away perhaps only 180 calories. What actually happens if you exchange glucose for fat is at first perhaps an apparent increase of tolerance or decrease of the insulin need. If a patient is on, say, 1500 calories, and you subtract 20 grams of carbohydrate and add 200 grams of fat, the first effect may be a lowering of the insulin dosage for at least a few days. Afterward you will find that the insulin dosage will creep up and the slow delayed effects of the fat will become more evident as the weeks and months go by. We have had plenty of examples of the harm resulting from adding calories in that fashion. One patient could be kept sugar-free on 40 units of insulin a day, but by substitutions which doubled his calories without changing the theoretical glucose value he reached a point where he was taking 140 units of insulin and still excreting 90 grams of glucose. It is easiest to see this result in the severe cases; therefore, they are the best for tests. But in all cases total calories must be considered, and food-stuffs cannot be interchanged on a mere basis of glucose content.

Ninth. It is not true that any special or artificial kinds of food can evade this law. Levulose, caramel, intarvin, glycerol, and other artificial or unusual forms of food have been introduced as things which might not form glucose in the metabolism, thus returning to the old notions of diet. These foods may not impose the same strain that carbohydrate does. Foods differ in this respect. The greatest strain on the pancreatic function is imposed by carbohydrate, the next by protein, and the least by fat. But even if the artificial foods may perhaps impose less strain than carbohydrate, they do not escape the law of total calories, and it is not true that you can give any food to diabetics without taking account of its caloric value.

Tenth. It is not true that the influence of body weight and obesity is yet explained by any known metabolic laws. We do not know why obesity predisposes to developing diabetes. Joslin especially has shown the fact statistically. Obesity or gain of weight also has a marked effect on the tolerance of diabetics. The tolerance is greatly increased by reducing the weight. Of course, as we increase the weight we increase metabolism, but as far as known the increased strain on the pancreatic function is out of all proportion to the increased metabolism. If you increase a patient's weight by ten, fifteen, or twenty pounds, you increase his metabolism appreciably, but in some cases you may increase the insulin requirement four or five times. The tissue he puts on is likely to be almost pure fat, and adipose tissue is not known to increase the metabolism greatly; but it seems to be this very adipose tissue which chiefly increases the insulin requirement. When a patient begins to lay on fat his insulin requirement goes up. The reason may be figured out some day in terms of metabolic laws, but up to the present the explanation seems not to have been found.

INSULIN TREATMENT

Turning to the subject of insulin, I shall mention a similar list of things, which, according to present evidence, are not true.

First. Insulin is not required in the majority of diabetic cases. It is easier and simpler to get along without it, and most cases are mild enough that you can get along without it.

Second. It is equally well known that insulin does not cure diabetes. We have tried maximum dosage in children with very mild or early cases, and have not succeeded in curing them; these children, like all other patients, have remained diabetics. In a few cases the tolerance does rise tremendously, so that insulin may be greatly reduced and sometimes stopped altogether. There is always the hope that in some rare cases the diabetes may come to an end, particularly if there is an acute or subacute pancreatitis underlying the diabetes. It is theoretically conceivable that if the pancreatitis gets better the patient may recover. But ordinarily the rule is, once a diabetic, always a diabetic; and that rule has not been broken by insulin.

Third. It is not true that insulin has any specific curative effect upon diabetic complications. If we become too optimistic on this subject we are likely to be disappointed. It was always true that if we controlled the diabetes the complications became better. We thus obtained good results in gangrene, without insulin. Insulin furnishes a quicker and surer means of arresting all complications; but if a patient has deep gangrene he still, as a rule, loses his foot. We saved some feet before we had insulin, and we do not save appreciably more of them nowadays with insulin, because there is the same basis of arteriosclerosis. We save some lives we could not save before, because patients can be kept sugar-free more readily, but insulin has no specific action on the gangrene. Sugar freedom obtained by insulin is no more important than sugar freedom obtained by diet in its effect on complications.

Fourth. It is not true that there is any practical method of giving insulin except by injection subcutaneously or intravenously. There has been interesting work done experimentally with the administration of insulin by various other ways, especially in animals. But from the practical standpoint it does not work, and if any absorption were obtained it would be too uncertain and irregular for practical purposes. Also, no other pancreatic preparation has been shown to have any effect. Pancreatic substance taken by mouth in any form, or proprietary remedies alleged to stimulate the pancreas or to act in some way other than insulin, have not sustained their claims and have no scientific basis.

Fifth. It is not true that any diabetic cases are refractory to insulin. It is interesting to watch the literature for reports of that kind. I felt pretty sure they would come from people who use high caloric diets and who do not recognize certain principles in diet. Those reports are coming in. One of the most noteworthy was published by Falta last July. He reports a case in which he gave insulin, as high as 160 units a day, and it did not affect the blood sugar when given either subcutaneously or intravenously. Therefore, he claims that this case is re-

fractory to insulin and assumes that it is not due to deficiency of insulin or of pancreatic function, and must be due to some other cause. If you study this case you will observe that, although during a few hours following his doses he did not find much fall of blood sugar, yet he admits that the total sugar excretion on insulin days was less than without it. Then, too, the patient is described as being of medium height and weighing approximately 200 pounds, decidedly obese. That kind of a result can be duplicated any day. By fattening a severely diabetic patient, you can get him into a condition where insulin can be poured in almost like water, and the largest doses will have minimal effects. If Falta's patient were brought down to a reasonable weight, it would probably be found that the case not only can be controlled by insulin, but is not very severe. Such difficulties are going to be encountered by a number of people who give fats and other foods in such quantities as to keep their patients obese. I mentioned our own experience where a patient took 140 units a day and still excreted as much as 90 grams of sugar a day.

Sixth. Following up the point just mentioned, it is not true that there is evidence of disturbance of any gland other than the pancreas in typical cases of diabetes. Insulin prepared from the pancreatic islands does control diabetes in every case, and no preparation from any gland other than the pancreas has the slightest influence on diabetes. Yet in spite of this discovery, the pluriglandists base an argument on the fact that you can give insulin to lower the blood sugar, and give adrenalin to bring it up. One lowers, the other raises; therefore, is there not an antagonism? and the answer is, no, there is not. In the first place we have no evidence that adrenalin is ever thrown into the blood stream in such quantities normally in the living body. Furthermore, there is no evidence of a true antagonism. Adrenalin tends to produce glucose from glycogen and thus throws sugar into the blood stream, but it does not cause inability to use glucose, which is the essential feature in diabetes. Furthermore, there is recent evidence that insulin does not serve specifically to build up glycogen, and under some circumstances actually reduces it. Therefore, no true antagonism exists between adrenalin and insulin, and there is no proof of any glandular antagonism in the body. Diabetes is purely a pancreatic disease.

Seventh. It is not true that the mechanism of insulin action is yet known. The theory of Winter and Smith that there is something peculiar in the character of the glucose, that the blood sugar in diabetes is chemically different from that of the normal organism, is not apparently gaining support. One of the most interesting future possibilities is that we may learn how insulin is related to the carbohydrate metabolism, or to the total metabolism. Even the toxic effect of insulin is not yet explained. One of the brilliant observations of the Toronto school was found in the symptom complex of hypoglycemia—the effect on the body of too little blood sugar. But insulin poisoning is not due strictly or solely to hypoglycemia. Your patient may show severe symptoms of collapse, or even unconsciousness or convulsions, and yet not have an extremely low blood sugar. We do not know what makes the

intoxication in such a case. We do know that glucose relieves it, regardless of the blood sugar level.

Eighth: It is not true that the insulin requirement is governed by the total metabolism. Exercise is a very powerful means of raising the total metabolism, but it rather lowers the insulin requirement. The patient taking heavy exercise does not need more insulin than before; he needs less. Whether insulin is related to the basal metabolism is not clearly proven. There is partial evidence in favor of the conception of basal metabolism being a deciding factor. In fasting, glycosuria is reduced, the insulin requirement is reduced and the basal metabolism is reduced. We do not know whether the fall in metabolism is the essential reason for the relief of the strain upon the pancreas. In the majority of cases when the basal metabolism is raised (e. g., by gain of weight, by hyperthyroidism or by fever) the tendency to glycosuria and the need for insulin is increased. But this suggestive evidence is not conclusive.

Ninth. It is not true that either the diet or the urine furnishes any uniform basis for calculating the insulin dosage. In the early days many conjectures were made that if there was a certain quantity of glucose in the urine or in the diet a certain number of units of insulin would be needed. That is not true. The only way to find out the insulin dosage is to try it. For instance, there is a difference according to the source of the glucose. If a patient shows glucose in the urine from adding carbohydrate to his diet, that is one thing; if he shows the same amount of sugar in the urine from adding high calories in the form of fat, that is very different. The latter form is much harder to clear up, and takes more insulin. Also the effect of complications is well known. Acidosis, for some reason, multiplies the insulin requirement. There is also an observation from Toronto which seems to be correct, that each unit of insulin becomes less effective as the total units are increased. If you give a patient 100 units of insulin, each unit is less effective per gram of glucose than if you give 10 units. There are other factors, but certainly there is clinical proof that only by testing the individual case can one decide how much insulin is needed.

Tenth. It is not true that there is any specific progressive pathological process in diabetes if the pancreatic function is saved from functional overstrain. Several years ago I put forward this doctrine, and I doubt if anybody believed it at that time. Now with insulin at hand, probably everybody will believe it, because with insulin we can relieve the strain upon the pancreatic function more easily and more thoroughly than could previously be done by diet. In severe cases it was formerly very difficult to keep the blood sugar down and clear up obvious signs of overstrain of the pancreatic islands. Now that this is done on a wide scale with insulin, everybody can see that the progressiveness of diabetes can be halted. The reason for progressiveness is found in the hydropic degeneration of islands of Langerhans, photographs of which you have seen passed around in this meeting. Hydropic degeneration is the vacuolation, swelling and destruction of the island cells, which results from functional overstrain. The islands get it only when they try to

work beyond their capacity. When that process is checked either by diet or by insulin, diabetes apparently does not progress.

PRACTICAL DETAILS

Altogether twenty points have been mentioned as not true, and it may be asked, "What is true?" There remains much room for individual judgment as to the method actually used, if a few basic principles are observed.

In the first place we prefer beginning with institutional treatment, which means that the patient generally remains in the hospital for two or three weeks. We believe the case can be studied better and the patient taught to care for himself better by being in an institution, and the period should not be too short or he loses the full benefit.

Then, using the same two headings, diet and insulin, I shall take up first, diet.

The first requisite is a doctor's ability to calculate a diet. If he cannot figure a diet in carbohydrate, protein and calories, he ought not to treat diabetes. Anybody can be a specialist if he will simply familiarize himself with the primary principles of diet, but if he will not take that trouble, he ought to send his diabetic patients to somebody else. But if he goes to this trouble he can treat diabetes more easily and also more successfully than can be done by following any hard and fast set of rules.

As regards proportions of the different foods, we believe that 60 to 80 grams (or more in mild cases) of carbohydrate and about the same of protein makes the most satisfying diet, is most conducive to comfort, strength and fidelity, and gives the widest margin of safety against acidosis. In a few cases lower carbohydrate and protein may be useful for reducing the dosage of insulin or avoiding it altogether. In all cases it is a matter of preference, not a choice between right and wrong, as to whether the diet contains high or low proportions of carbohydrate or fat, provided the total calories are suitably restricted. If you believe in carbohydrate and protein rations as low as 30 or 40 grams per day you may treat diabetes very efficiently with them, but comparative tests will show you that in the long run little insulin is saved and the patients are distinctly less comfortable than with the more normally balanced diet above mentioned.

As regards total calories, our diets are such as to keep the patients not above the normal average weight. Sometimes they are fully up to the normal, and frequently five or ten pounds below the normal average, because in this way less burden is placed upon the pancreas, and on the whole the patients do better. The influence of the total calories and body weight far exceeds the influence of a few grams more or less of carbohydrate or protein.

Then, as regards insulin, we use it when there are severe complications, or when the patient cannot gain tolerance for an adequate diet without insulin. Blood sugar determinations are desirable. Some persons have tried substituting other tests, particularly the new quantitative methods for sugar in normal urine, but I believe the consensus of opinion is that the best method is that of blood sugar tests. They may not be absolutely indispensable, but they

are extremely valuable and are generally the best basis of treatment.

The dosage of insulin is that which will keep the patient completely free from glycosuria, and the blood sugar as nearly normal as possible. It cannot always be normal. But the patient with glycosuria or extremely high blood sugar is liable to infections, and is more apt to develop acidosis and perhaps die suddenly. With existing glycosuria, even though the patient is on high insulin dosage, there is very serious danger of a sudden outbreak of acidosis, causing death within forty-eight hours.

The total daily dosage is divided into a number of injections, according to the size of the total dose. We practically never give more than 20 units in one dose. We seldom give less than two doses per day, even if the total number of units of insulin is low. Insulin may be given with meals; that is the commonest way, but in some of the severest cases we have published a method of giving it about one hour before breakfast for the first dose, and an hour or two after supper for the third dose, as that plan shortens the night period. This reduces the tendency to fluctuation in the blood sugar, and there is no particular reason why every dose should be given with a meal.

Also the plan is to keep the total insulin as low as possible. If it rises too high, for example, above 100 units, it is almost impossible to keep the patient free from glycosuria or hypoglycemia, one or the other. The only remedy is to cut down the insulin dosage. The way to do that is to reduce the patient's weight. Therefore, as far as possible, we use a low caloric diet to keep the body weight somewhat below normal, and in that way ordinarily we keep the insulin dosage down, so as to allow the case to run smoothly. The patient who can use the least insulin is the best off in the long run.

The special treatment of complications cannot be gone into in detail, partly because it has been covered so often before.

The point I would emphasize, in conclusion, is that all the evidence, theoretical and practical, indicates that if patients are handled properly in these two respects—diet and insulin—every case of diabetes can be controlled, and this control can be maintained without downward progress and without any deaths occurring on account of diabetes.

Some Causes of Ageing—"We doubt if we can ever discover means of greatly lengthening life," concludes Malford W. Thewlis (Medical Journal and Record). "There are many factors," continues this author, "at play in the production of premature senility, such as an abnormal mode of living, and the excitement and worry of modern life. Normal old age seems to be a mystery, as far as its actual cause is concerned. There seems to be a law of Nature which brings about old age just as it brings birth in a given length of time, and puberty at another. If Rolleston is right, there is a more or less definite cycle during which cells multiply and after which they cease to do so. It seems to be the best explanation we have of the cause of normal old age. As for the causes of abnormal old age, to repeat, numerous factors must be considered."

"... There is no greater power in the realm of man today than the printing press, and it would be infinitely more powerful and productive of results if those whose thoughts go out to millions through it would write in a spirit of service and in the sense of stewardship."—Edward W. Bok.

CAESAREAN SECTION FOR PELVIC OBSTRUCTION

By ALICE F. MAXWELL, M. D., San Francisco

Contracted pelvis in white women are comparatively rare—the degree of contraction in the large majority of cases is such that spontaneous pelvic delivery is the rule. This is the most advantageous method of labor for mother and child. Caesarean section, under ideal circumstances, carries a definite maternal mortality and must not be regarded as a panacea for obstetrical complications.

DISCUSSION by Titian Coffey, Los Angeles; L. I. Breitstein, San Francisco; Charles E. French, San Francisco; Edward N. Eaver, Oakland.

BEFORE Sanger introduced the method of suturing the uterus, the appalling maternal mortality which followed Caesarean section was the factor which limited its employment to cases in which no other method was available to secure a living child. Pelvic obstruction was the one and only indication which justified its performance.

As the result of the increasing safety of modern abdominal surgery, and because of the ease and simplicity with which the operation can be done at the present time, an ever-growing number of fancy and flimsy indications are advanced for its employment. Varicose veins, asthma, abdominal pain, epilepsy, breech, hydramnios, etc., as indications serve to illustrate the inadequate conception of the real danger of Caesarean section. This loss of perspective and unsuitable widening of its applications reflect the lack of even the fundamental principles of obstetrical art or else an unwillingness on the part of the obstetrician to sacrifice himself, or to give of his time and thought in an effort to assist a woman to deliver herself by the natural passages. The impression in the mind of many medically trained men that Caesarean section is a panacea for all obstetrical problems suggests a serious lack of knowledge of the inherent danger of abdominal surgery to the pregnant woman. Statistics from large clinics have shown that, even under ideal circumstances, the maternal mortality is 2 to 4 per cent if performed upon women in labor, or after vaginal attempts at delivery have been made the mortality varies from 11 to 34 per cent.

Arnold Roux, in 1911, showed that: 245 cases not in labor, 3.8 per cent mortality; 274 cases in labor, membranes intact, 2.6 per cent mortality; 166 cases in labor, membranes ruptured, 10.8 per cent mortality; 64 cases frequent exam. or forceps, 34.3 per cent mortality.

Guy's Hospital report of 121 cases of Caesarean section, from the years 1910-1920, show mortality of 6.8 per cent.

Holland and Kerr's figures from Great Britain and Ireland, from the years 1911-1920, in 4000 sections show that: 1200 cases not in labor, 1.6 per cent mortality; 389 cases early in labor, 1.8 per cent mortality; 220 cases late in labor, 10 per cent mortality; 35 cases after induction of labor, 14 per cent mortality; 107 cases, forceps or craniotomy, 27 per cent mortality.

Williams, in 1921, analyzing 183 sections done in 20,000 deliveries, had a gross mortality of 5.51 per cent—net 3.5 per cent; 4 per cent in conserva-

tive Caesarean, and 1.8 per cent in Porro sections. Data furnished by questionnaires sent to hospitals throughout California disclosed a startling situation, namely, in 1922, there was a 10 per cent maternal mortality following Caesarean section.

Newell, as the result of his investigations of the mortality of Caesarean section in some of the smaller communities near Boston, concluded that the operation as performed by local operators for alleged indications was the most fatal of surgical procedures.

Any break in surgical technique of the corps of assistants needed at the operation will result in disaster to the woman. Any surgeon may have a long series of cases without any deaths, but, given the opportunity, in the end he cannot escape the inevitable minimal mortality.

If these facts are borne in mind, it would seem imperative to consider the indications which actually warrant our employing a procedure which admits at least 2 to 4 per cent mortality under the most ideal and advantageous situations, and a death rate of 35 per cent plus in unfavorably modifying circumstances.

The most frequent and important indication for Caesarean section is pelvic obstruction.

Admitting that the size of the birth canal has a distinct bearing on labor, it must not be forgotten that the vital consideration, nevertheless, is the relative proportion which the passenger bears to the passage, which is, after all, the determining factor of a particular labor. It may be no more difficult for an undersized child to pass through a contracted birth canal than an overdeveloped child to pass through a normal pelvis. The strength of the uterine contractions has also a definite bearing on the outcome of a labor, for, given two women with the same degree of disproportion between the pelvis and child, the efficiency of the labor pains will be the deciding factor in effecting a spontaneous labor in one, or forcing an operative delivery in the other. Pelvimetry serves to demonstrate the degree of adequacy or inadequacy of the pelvis; the size of the child, its position and the vis-a-tergo must enter into the calculation of the proper treatment of an individual case.

Pelvimetry indicates that the frequency of contracted pelvis varies greatly. Thus, the German clinics give a frequency of 8.24 per cent; the Austrian 2.1 per cent, and the French 5.1 per cent. In America, Williams noted contracted pelvis in 24.4 per cent, the proportion in the black race being three times as often as the white—40.9 per cent and 13.4 per cent, respectively.

Crossen reports 1800 cases with 1.7 per cent showing pelvic contraction. In the University of California series of 4604 cases, there were 3.5 per cent with pelvic contractions.

It is generally conceded that 80 per cent of women with contracted pelvis, even with the impossible or doubtful types, will deliver themselves spontaneously if allowed to go into labor. Thus Schauta, in 5288 cases of contracted pelvis among 39,397 births, had a spontaneous labor in 77.8 per cent, with a maternal mortality of .09 per cent and a foetal of 2.2 per cent.

Holland and Kerr's review of 4000 sections in

Great Britain and Ireland showed that 3372 sections were done for contracted pelvis, with a mortality of 4.1 per cent. Guy's Hospital reports in 1920, 121 cases with contracted pelvis as indication 107 times; Williams, in list of 183 sections in 20,000 deliveries, found disproportion of the pelvis furnished the indication in 144 cases (78 per cent).

In our series of 4604 cases at the University of California Hospital, 3.5 per cent (162) were found to have contracted pelvis. Yet 65 per cent of these women were potentially spontaneous, if we deduct the low forceps deliveries in which there was no dystocia due to the pelvis, and Caesarean section was performed only twenty-one times for contracted pelvis.

That eight out of ten women will deliver spontaneously must be emphasized and should serve to impress upon us the necessity of exercising calm judgment in handling these women; it should also prevent meddlesome interference early in labor which may block this hoped-for outcome in the large majority, or in the small less fortunate group render impossible sane surgical treatment. We all agree that it is best for the woman to deliver herself spontaneously, for no other method is associated with so little danger to the mother and child.

If contracted pelvis occur in about 10 per cent of white women, and the large majority of such contractures are compatible with spontaneous pelvic delivery, it is apparent that even in a large clinic Caesarean section will be rarely performed for pelvic obstruction.

However, there are absolute indications for the performance of Caesarean section, namely, when the abdominal route offers the only possibility of saving the mother or child. It is universally agreed that when the true conjugate measures 5 cm. or less, abdominal section is essential to accomplish delivery, regardless of the presence of uterine infection, for such degree of contraction renders impossible delivery by the natural passages of a foetus, even though crushed. With our present-day prenatal observations and pelvimetry, such a degree of contraction cannot be overlooked and its recognition at once establishes the necessity for surgical treatment at term or before the woman has been allowed to go into labor; in other words, to operate under ideal circumstances. Then the operation is an invaluable procedure and undoubtedly has saved many mothers and children who, with other treatment, would be hopelessly doomed. This type, in whom natural delivery is impossible, forms a very small number, considering the frequency of contracted pelvis, for we emphasize in the vast majority of cases spontaneous labor at term is mechanically possible. Only a small group in whom the issue is doubtful may require the nicest judgment in treatment to safeguard the mother and child's best interest.

Relative indications for Caesarean section are afforded by a pelvis with a true conjugate of such length that it is practically impossible to deliver a non-mutilated child through the bony pelvis. With this degree of contraction, section at term will meet the best interests of both patients. Even with less marked degree of contraction, i. e., 7.5 to 8.5 cm.

in flat pelvis and 7.5 to 9 cm. in generally contracted, the operation is frequently done as an elective procedure, for, while spontaneous labor is possible in a large proportion of this class, it will be exceedingly difficult to prognosticate the course of labor in advance—for the efficiency of the uterine contractions is the undetermined variable and many mothers and children may be hopelessly injured or lost, should this last factor be weak and infrequent in character. The best interest of the mother will not be conserved if the mere possibility of pelvic delivery counterbalances the physical and psychic trauma of a severe labor with the attending tears of the supporting structures of the pelvic organs and resulting prolonged invalidism.

In these borderline cases, helpful conclusions regarding the possible outcome of labor can be obtained by noting the presence or absence of overriding of the head on the symphysis. If the head does not override the brim and can be pushed into the pelvis (under anesthesia, if necessary to secure relaxation), it is practically certain that, with ordinary labor pains, a pelvic delivery can be looked for. However, with overriding or inability to push the head into the brim, the outcome is not so certain, and modifying factors must come up for consideration of the treatment of each individual case. If, for example, we have an elderly primipara with this pelvic condition, a section at the proper time will insure a baby with the irreducible minimum of any surgical operation to this mother. The same situation occurring in a woman who gives a history of previous obstetrical disasters will warrant a section if we admit the tendency to enlargement of successive children. Careful measurement of the head and comparison with the pelvis will, of course, materially modify our judgment, although a history of repeated foetal death from pelvic dystocia, even with slight degree of contraction, will influence our choice toward section as the conservative method of delivery for mother and child.

The position which the presenting part bears to the inlet is significant. A face or brow presentation indicates definite and maladjustment; a posterior position of the head may be a modifying factor which may definitely influence our decision. The rigidity of the maternal soft parts and cervix, the moulding possibilities of the child's head, as affected by width of sutures and fontanelles as demonstrated by rectal palpation, the time of rupture of the membranes and the efficiency of the uterine contractions must all come up for consideration.

The effect of a long, hard labor upon the particular woman with a borderline pelvis is of great importance, some patients being so nervously and physically constituted that even a moderate strain will often impair the health for a period of many months or years. Women with cardiac weakness should always be spared the possibility of a decompensation resulting from prolonged labor. If we feel that the physical or nervous stamina is below par or that severe exhaustion after a moderately difficult labor will follow the effort to deliver by the natural passages, a section will be the conservative procedure.

Because it is not always possible to decide upon the proper course, and because we recognize our

fallibility in prognosticating the outcome of a particular case, the test of labor is frequently applied, for it affords a strong hint as to the probable outcome. If we find that labor is initiated by strong uterine contractions, that the cervix is dilating steadily, as determined by rectal examinations which should be definitely limited in number (for we do not admit this method of examination is done without danger of introducing infection into the cervix) and that the head is fixing and moulding through the pelvis, we feel that the patient should be given the opportunity to deliver herself. If, however, early in labor some complicating factors, such as inefficient, weak contractions, face presentation developing during labor, premature rupture of the membranes with only beginning cervical dilatation should be added to the complexity of the problem, we must be prepared to modify our plan of treatment. Early interference in labor with the woman not compromised by vaginal examination, with the cervix just beginning to dilate, particularly if the membranes are intact, practically adds nothing to the danger of abdominal delivery. We do not feel, however, that when the test of labor has been allowed to extend over a period of several hours, even in the absence of vaginal examinations, that the ordinary conservative section can be considered as the safe alternative method of delivery. Every hour of labor adds ten-fold to the potentiality of infection. Under these circumstances, we cannot be justified in submitting a patient to the risk of a procedure which the most conservative figures show will doom at least one out of ten mothers.

In considering pelvic obstruction as an indication for section, contractions of the outlet must not be overlooked. Funnel pelvis is the most common type of pelvis abnormality in white women, according to Williams. In these cases, the pelvis assumes male characteristics, the pelvic arch is narrowed, with resulting limitation of space available for the foetal head beneath the symphysis. The posterior segment of the outlet here must be accurately determined, for the head must be accommodated largely by the area between the tuber ischii and the lip of the coccyx. Pelvimetry will determine the degree of contraction, but again modifying factors must help to make the decision. The size of the child, its position, age of the patient, rigidity of the soft parts, are important in determining the policy of conducting the particular case. Pubiotomy must always come up for consideration in treatment of contractions of the outlet, for the widening of the outlet depends directly upon the amount of separation of the pubic bone. With the patient advanced in labor and the child obstructed at the outlet, Caesarean section cannot be compared to pubiotomy as the conservative method.

In conclusion, I would like to stress the following:

Contracted pelvis in white women are comparatively rare. The degree of contraction in the large majority of cases is such that spontaneous pelvic delivery is the rule. This is the most advantageous method of labor for mother and child. Caesarean section, under ideal circumstances, carries a definite

maternal mortality and must not be regarded as a panacea for obstetrical complications.

University of California Medical School.

DISCUSSION

TITIAN COFFEY, M. D. (1136 West Sixth Street, Los Angeles)—Two of the most valuable points brought out in Doctor Maxwell's paper that appeal to me are, first, the incredible and unheard of so-called indications for Caesarean section that are being used today all over the country; second, the fact that a large majority of cases of contracted pelvis deliver spontaneously at full term. I am glad she has stressed these points, for they are of the utmost importance and should be constantly borne in mind when studying the parturient woman.

Caesarean section at present is done for almost any indication and I for one would be glad to see the pendulum swing back and a more sane attitude taken as regards relative indications.

The positive indications are few and well recognized and need not be referred to but the border line cases are the ones that demand a nicety of judgment and utmost skill on the part of the obstetrician in determining what is best for the mother and child.

Disregarding extreme emergencies such as eclampsia, placenta previa, etc., that apparently may present a relative indication and then almost instantly change into a positive one, it is our duty to so study the pelvic cavity before confinement and the relation of the presenting part thereto, that we have pretty well made up our minds as to the character of labor a given woman will have and what our procedure is likely to be to effect delivery if complications arise. In a young primipara, upon first examination in beginning pregnancy, when the parts are tight and snug we are apt to underestimate the size of the pelvic cavity and think section will be necessary at the end. Many patients are told this or else they are told they can never have children as they are too small.

It is amazing as pregnancy goes on how the parts soften and how much larger the pelvic cavity becomes a few weeks before full term. We may still find the occiput high or attempting to engage at the brim, but we now have a softened enlarged pelvic cavity that puts us in a position to make a much better estimate as to whether or not the head will go through than at our earlier examination.

It is a good working rule that if the promontory of the sacrum cannot be felt by the examining middle finger an average-sized baby will go through that given cavity.

Especially toward the last, all doubtful cases should be kept under close observation so they may be classified and treated as "operations of choice" rather than thrown into the haphazard class and any old chance taken. Considering the appalling mortality in cases that have been neglected, when the golden opportunity has been lost by injudicious "man-handling," certainly version and extraction is a preferable procedure to section.

In other words, the vast majority of cases, by careful preliminary study, put us in a position to know our method of delivery long before they become even relative cases.

Induction of premature labor two to three weeks in advance of full term or induction of labor at term is not done frequently enough. Doubtful cases should never be allowed to go over time. By the induction of labor in suitable cases many mothers will be saved section.

Doctor Maxwell's point that a large majority of cases of contracted pelvis deliver spontaneously is well taken and should never be lost sight of.

L. I. BREITSTEIN, M. D. (350 Post Street, San Francisco)—Doctor Maxwell's paper is a very important contribution and should be studied by every one doing obstetrics. The statistics that she quotes, namely, a maternal death-rate in elected and clean cases under ideal conditions averaging from 2 to 4 per cent, and in cases where women were in labor or after vaginal attempts at delivery have been made, varying from 11 to 34 per cent, are simply appalling. It certainly appears as a crying indictment against the Caesarean section operation. On closer study, the trouble is not with the Caesarean section

operation, but in the judgment of men doing obstetrics. I feel sure we can reduce the maternal death-rate if we would approach the problem from the following angle: Not so much from the stand that we should do a Caesarean section, but from the stand when should we not do a Caesarean section. If certain rules were laid down contra-indicating this operation, and the hospital requirement demanding consultation before this operation is permitted, I am sure the number of mothers dying from Caesarian section would rapidly diminish.

In my service at Mt. Zion Hospital a good many of our maternity cases are drawn from women who were born in Russia, Balkan States, Turkey, Armenia, Palestine and Egypt. We find our average of cases of contracted pelvis runs higher than at the University of California Hospital. The types we see are:

1. General contracted.
2. Flat rachitic with wide contracted outlet.
3. Masculine type with contracted outlet.

Our working rule is as follows:

1. For elected and absolute clean cases we employ the classical Caesarean section, using the high incision.
2. For cases which have been given the test of labor or where membranes have prematurely ruptured and thirty-six hours have elapsed, or in cases where one or two vaginal examinations have been made, even under aseptic technique, these cases are considered as potentially infected, and we resort to the low cervical section.
3. All other cases not included under the above two heads, with the exception of the absolute indication, are not sectioned, but delivered from below, even if we have to resort to a craneotomy. I am happy to say our maternal mortality averages from 1 to 2 per cent.

CHARLES E. FRENCH, M. D. (Flood Building, San Francisco)—There are a certain number of women of the upper class, somewhat advanced in years, who request a Caesarean section rather than undergo the pains of labor. They know something of the operation, have perhaps seen its brilliant results in friends, and have been assured by medical men that in uncomplicated cases, if done before the onset of labor, it is no more serious than an interval operation for appendicitis. If the results of these carefully gathered statistics, taken from such a diversity of sources, were presented to such women they would be more reticent about having this operation. Nitrous oxid analgesia, with version or forceps, if necessary, means perhaps a little more pain, but at a greatly lessened risk.

I believe that a damaged heart is used as an indication for Caesarean more frequently than is absolutely necessary. I have been amazed more than once to see how well a badly damaged heart could accommodate itself to labor in patients who have refused a Caesarean. As an added argument in heart cases it is proposed to sterilize the patient at the same time. I think that this should be disregarded in making a decision to operate. We operate to save mother and child; the future should not be allowed to influence that object. If it is deemed best to sterilize her it can be done at a subsequent laparotomy with far less risk.

Doctor Coffey's contention that premature labor is not induced often enough should be strongly emphasized. The induction of labor several weeks in advance of full term in cases of moderately contracted pelvis is preferable to a section at term. The mortality rate should be almost nothing and it is a simpler and safer procedure in the hands of the general practitioner who does the great bulk of the obstetrical work.

Doctor Breistein's suggestion that it be a hospital requirement to have a consultation before a Caesarean operation is good. Why not also require every operator to report such operations to the monthly staff meeting for discussion, the same as we do with all mortalities?

EDWARD N. EWER, M. D. (251 Moss Avenue, Oakland)—Obstetricians who take pride in the art of their subject will agree that Caesareans are over-much the fashion. This condition came about largely through rather general adoption of the operation for quick delivery in eclampsia. Carl Braun had stated the convulsions usually stopped after delivery. Dührssen claimed this result in 94 per cent and Ohlshausen in 85 per cent. What more natural than that Caesarean, an easy

quick operation, should look attractive when accouchment force and high forceps had become discredited.

Caesarean for eclampsia has accounted for a mortality of 16 per cent in well-equipped maternities in Great Britain, and 32 per cent in the country at large (Fitzgibbon). At the Rotunda, where they do not Caesareanize, the death rate for twenty years under their conservative method of treatment has been only 8 per cent. Equally good results are reported from many sources. In view of these facts, it is high time for Caesarean section as routine treatment for eclampsia during the height of the toxæmia to be frowned upon. Next the operation was seized upon for the solution of almost every obstetric difficulty, and the dire results are shown in Doctor Maxwell's figures.

Distocias, due to faulty rotation, like deep transverse arrest, are too often treated by section. I find with the Kielland forceps their handling from below is usually easy and safe.

I believe, with careful judgment, the indications for Caesarean section may be broadened to include many cases of placenta previa.

The indications in pelvic obstruction as outlined in Doctor Maxwell's paper are sound in every particular, and should be carefully studied and adhered to.

I wish to put in a word for the low Caesarean, which, I believe, has many advantages over the classical variety. If it is safer in the presence of infection, it is to be preferred in all cases, for if 50 per cent of all Caesareans are attended with a febrile puerperium, as is generally stated, the possibility of infection must always be conceded. Furthermore, the dictum "once a Caesarean, always a Caesarean" need not be urged for the low operation. There is no more danger of future rupture than there is after vaginal hysterotomy.

CLASSIFICATION AND RESULTS OF TREATMENT OF HAY-FEVER *

By FRANK R. MENAGH, M. D., *Detroit, Mich.*, and
GEORGE M. FISTER, M. D., *Brigham, Utah*

(From the Department of Cutaneous Medicine, Henry Ford Hospital, Detroit, Michigan)

A study of 190 patients with allergic coryza.

Patients with vaso-motor rhinitis and non-seasonal hay-fever are in most cases sensitive to food or animal emanation proteins.

The intradermal is more reliable than the cutaneous method for testing sensitiveness.

A patient not sufficiently relieved by pre-seasonal treatment should be treated through the season, and the following year the patient should receive an increased amount of pollen extract.

OUR object in presenting this paper is first, to classify the patients referred to the department because of symptoms of hay-fever; second, to give the results of our treatment.

By hay-fever we mean allergic coryza caused by pollens, which indicates a hypersensitive reaction on the part of the patient to pollen protein. Cooke designates by the term "allergic coryza" that symptom complex which arises from a hypersensitiveness of the mucous membrane of the upper respiratory tract and usually of the eye.

Vaso-motor rhinitis, a term commonly used, merely refers to a pathological condition, and when these patients are studied, most are found hypersensitive to proteins. Hansel, in a group of one hundred cases of non-seasonal vaso-motor rhinitis, found approximately half of them to be sensitive to various proteins.

Dunbar, in 1905, was the first to use plant pollen in the treatment of hay-fever. He attempted to pro-

*Presented at the 1924 Annual Meeting of the Utah Medical Association, Salt Lake.

duce an anti-toxin in the horse. Since that time the literature and work on protein sensitization has been most extensive, and has rapidly changed our conception of the etiology of hay-fever and asthma.

The natural result of such rapid advance has been considerable confusion. One of the questions presented is that of anaphylaxis. Is hay-fever an anaphylaxis phenomena? The view advanced by Coca seems most acceptable. The word "anaphylaxis" is reserved by him for those reactions produced in the human, or in the animal, after an artificial hypersensitiveness has been produced; while allergy applies to the reactions occurring in individuals naturally hypersensitive from the absorption of the specific protein. Anaphylaxis is a true antigen-antibody reaction. There is no proof that allergy is of this specific nature. This distinction is fundamental when considered from the standpoint of therapy. In anaphylaxis complete desensitization is always possible and perhaps permanent. In allergy desensitization is only partial, and has not been found to be permanent.

Because of this essential difference, Cooke proposed the word "hyposensitization" to distinguish the lessened sensitiveness induced in allergy from the state of desensitization in anaphylaxis. We have no definite knowledge of what actually takes place in the process of hyposensitization.

We have adopted a classification of coryza, combining those used by Cooke and Walker. This includes coryza of both allergic and non-allergic etiology. This paper does not consider any cases or study of the non-allergic coryza.

The role of calcium metabolism in hay-fever and other allergic conditions is of interest. Pottenger is of the opinion that in asthma particularly there is a calcium deficiency which makes the neuro-cellular mechanism hyperirritable. Novak and Hollander, in their study, conclude "that certain cases of hay-fever and asthma show a low blood calcium, but that calcium therapy alone does not influence these conditions." There is, however, a possibility that calcium thyroid and parathyroid metabolism may be definitely associated with protein sensitization.

We can dismiss the role of bacterial proteins as a cause of hay-fever in our cases, because we had no patients in whom absorption of bacterial proteins was proven to be the cause of the clinical symptoms. Autogenous vaccines were used in some cases with marked benefit, but we do not consider their action as allergic.

METHODS OF DIAGNOSIS AND TREATMENT

Diagnosis—The success or failure in treatment of hay-fever is naturally dependent on proper diagnosis as to causative agent. A careful history is of great assistance, giving as it does much important information as to the age of onset, duration, family history, seasonal character of symptoms, date of onset, etc. Most of the patients were between 20 and 40 years of age, while the duration of symptoms were in the largest percentage of cases from one to twenty years.

It is estimated that 10 per cent of all persons are sensitive to proteins, 1 per cent being sensitive to pollens. Of these, about 40 per cent (in our service 34.7 per cent) gave a history of direct in-

heritance of allergy. Fifty-two and one-tenth per cent gave a history of other allergic symptoms of asthma, eczema, and urticaria. A careful physical examination is always done. Special care is taken in the examination of the nose and throat, and any obstruction is cared for surgically. Hay-fever per se is not sufficient cause for intranasal surgery.

According to the history and date of onset of symptoms, the patients are grouped. The time of appearance of the predominating fall type of hay-fever is August 15, and it lasts until frost. The spring type lasts from approximately May 30 to July 20. The mixed group had symptoms of hay-fever both spring and fall.

The patients classified as non-seasonal had symptoms of hay-fever, but their time of appearance had no connection with the seasons. The potential group were patients sensitive to pollen, but who had no history of hay-fever. We had no patients with hay-fever due to tree pollen. None of the patients had history of onset of symptoms at time of pollination of trees. The time of hay-fever varies with the locality and time of pollination. Local botanical surveys are important in determining these factors, and the abundance of the various pollens.

Our methods in testing for sensitiveness to foreign proteins are both cutaneous and intradermal. Food and animal emanation proteins are usually applied by the cutaneous methods as follows: An abrasion is made by the Von Pirquet scarifier, and on this area is placed the dry protein extract. A drop of one-tenth normal sodium hydroxide is added, making a solution of the protein. If there are no indications other than a history of seasonal hay-fever, approximately fifteen to twenty cutaneous tests are applied. Where indicated, as in the non-seasonal hay-fever, as many as ninety cutaneous tests have been applied.

The intradermal method is carried out with a tuberculin syringe and a solution of the proteins, 2 minims of a 1-500 solution of the protein being used. It is introduced into the superficial layers of the skin. In male patients these tests are applied on the flexor surface of the forearm; female patients, the anterior aspect of the thigh. We have found that the intradermal method will often give a positive reaction when the cutaneous test is negative. A positive test with either method is indicated by the appearance of an urticarial wheal with pseudopos. In reading our results, we have found that it is impossible to adhere to any fixed rule with regard to the wheal reaction. One individual will give a wheal reaction of 1½ cm. in diameter and with no pseudopos, while another individual, no more liable to develop symptoms from the same group of pollens, will give a 3 cm. wheal reaction with numerous pseudopos.

We have found that it is a valuable criterion to distinguish between the various tests made, and the proteins to which the patients does not react acting as controls. Where numerous tests are applied in a very sensitive individual, considerable reaction may appear both general and local. When this does occur, the prompt administration of adrenalin in amounts up to 2 cc. (intravenous if necessary) will usually prevent any serious consequences; although Lamson has recorded two deaths from the intradermal protein tests.

The pollen, or proteins, to which the patients show the greatest amount of reaction are the ones most apt to give symptoms. Naturally, wind-borne pollens are usually at fault. Nevertheless, patients at times show definite hay-fever reactions to pollens, not wind-borne, from which they come in contact, such as that of dandelion, goldenrod, and rose.

It is important that all pollens to which the patient reacts should be known, as the treatment with one pollen does not protect against another, in spite of the frequent statements to the contrary. As Bern-ton has shown in such a closely related group as the short and giant ragweeds, treatment with one does not give protection against the other. Of our 130 cases of fall hay-fever, all except one reacted to pollen of the short ragweed. In all but one case, ragweed pollen, either alone or in conjunction with other pollens, was used for treatment of this group.

The spring hay-fever in this vicinity is largely due to timothy, June grass or red-top pollens. The mixed group is a combination of both spring and fall pollens.

METHOD OF TREATMENT

In our treatment of the patients with hay-fever (seasonal allergic coryza) we have depended entirely on hyposensitization with the pollen extract. From the clinical data and sensitization tests the pollens responsible for the patient's hay-fever are determined, and extracts are used for treatment.

We offer nothing particularly new, but suggest simplicity in the treatment of hay-fever patients. Success of treatment can best be judged by clinical results and the patient's eagerness to return for therapy each season. In 1921, twenty-one patients were treated for seasonal hay-fever. Of this number, eleven, or 52 per cent, returned for treatment in 1922 and the same number again in 1923. In 1922, a total of forty patients were treated. Of this number thirty-one, or 77 per cent, returned for treatment in 1923, and most of these patients are again returning for treatment in 1924. When we consider many patients probably left the city and some were referred to their local physician for treatment, the percentage of returned patients is unusually high. There were no "cures." The freedom from hay-fever, as produced by hyposensitization with protein extract, is only temporary. Protein treatment must be resumed each season. It is possible that continued pre-seasonal treatment may develop a partial permanent tolerance for the offending pollen proteins.

To date we have used the acetone insoluble residue of the pollens in making our extracts. This season, 1924, we are using the method described by Coco. It is beyond the purpose of this paper to discuss the various methods of preparation of the extract. However, in order to obtain satisfactory clinical results it is absolutely necessary that one know the strength of the solutions used, graduated to an adopted standard. The nitrogen standard basis, assuming necessary precautions are taken to prevent deterioration of the extract, has many advantages, and more accuracy in dosage is possible.

In the cases reported we attempted to simplify the treatment and conserve the time of the patient

by starting treatment with a 1:10,000 dilution of the pollen extract. A 1:100 solution of the pollen extract is prepared by taking 0.1 gram of the acetone insoluble residue in 1 cc. of normal saline to which is added a drop of creosote. From this solution, strengths of 1:500, 1:1000, 1:5000 and 1:10,000 are prepared by addition of the indicated amounts of normal saline.

It has been our experience that it is perfectly safe and reasonable to treat patients with more than one pollen extract, if indicated.

The average initial dose in treatment has been 0.3 of a cubic centimeter of the 1:10,000 pollen extract solution. The dose is increased according to the patient's tolerance. If reactions occur, no increase in the amount of pollen extract is given at the next treatment. Adrenalin given with the pollen extract does not affect the success of the treatment. We have considered no patient sufficiently treated who has not received at least one subcutaneous injection of 0.5 cc. of the 1:100 pollen extract. The average number of injections required to reach this maximum injection was ten. We have no severe general or local reactions. Minor reactions of urticaria, hay-fever, or asthma were controlled by adrenalin.

The fall group of patients being the larger in number, the results can be considered a better average.

The best method of treatment is pre-seasonal, finishing the course of injections at the approximate date of beginning of hay-fever season. If the patient is not fully relieved, the treatment should be continued through the pollen season. Patients who appear for treatment during the season are treated in the same manner, except the dose of pollen extract used is smaller and the increase in amount is less rapid. It is surprising the amount of relief these patients receive from this seasonal treatment. If a patient treated pre-seasonal does not have sufficient relief, we continue the treatment throughout the season.

In regard to the patients classified as potential hay-fever subjects, no treatment was indicated. It is very possible, however, that most of these cases would develop clinical hay-fever if they came in contact with sufficient of the offending pollens. As long as their environment prevents this, and the local resistance in the upper respiratory tract is not lowered, they will probably continue to be free of hay-fever symptoms. The group of patients with symptoms of hay-fever, due to foods and animal emanation, were not treated. Hay-fever of this nature is best illustrated by case histories.

CASE A. F.—Came for relief of frequent head colds and marked sneezing. The spells of sneezing were most frequent and distressing at time of arising in the morning. Sensitization tests were negative to pollens, but were markedly positive to chicken feathers, goose feathers, and dog hair. Removal of contact with feather pillows gave relief. Hyposensitization should be considered if symptoms continue to the point of uncomfortableness.

CASE A. C.—Woman, age 50. Was first seen in the nose and throat department because of a persistent vasomotor rhinitis, with irritating nasal discharge. Protein sensitization tests were entirely negative, except for a characteristic reaction to the intradermal test with whole milk protein. Patient discontinued the use of milk and milk products, with complete relief. These illustrate well

allergic coryza due to proteins of foods or animal emanation.

One of the most interesting cases in the potential group of hay-fever patients was referred because of epilepsy (we have carried out protein sensitization tests on a large number of these patients). This patient was sensitive to ragweed, timothy, several food and animal emanation proteins. In this case patient had an attack of grand mal immediately after the sensitization test. Since removing contact with the positive proteins, however, this patient had only one light attack over a period of two months.

Further case histories are given to illustrate the other groups:

CASE A. M.—Boy, age 15, appeared with hay-fever symptoms of three days' duration, with no previous hay-fever. Protein sensitization tests were negative, except for dandelion. No treatment was given, except instructions to avoid contact with dandelion. No further hay-fever occurred.

CASE J. M.—Male, age 70. Hay-fever of twelve years' duration, sensitive to ragweed and rye. Treatment was completed June 25, a date too early to afford protection against fall hay-fever. Patient returned August 20 with hay-fever.

CASE W. E.—Fifty-five years old. Active pulmonary tuberculosis. Hay-fever of twenty years' duration, sensitive to ragweed and timothy pollen. Had better than 75 per cent relief. There was no aggravation of pulmonary condition, although patient had reaction to one or more treatments, with resulting generalized urticaria.

CASE J. S.—Fall hay-fever, sensitive to ragweed pollens. Came to clinic August 1. Stated he had finished treatment elsewhere this year for fall hay-fever. Gave a marked local reaction with generalized symptoms of hay-fever to an intradermal injection to 0.2 minim of 1:1000 solution of ragweed, which indicated treatment had not been completed.

SUMMARY AND CONCLUSION

1. A study of 190 patients with allergic coryza is presented.
2. The predominating type of hay-fever found in this vicinity is of the fall type, and in practically all cases due to the pollen of the short ragweed.
3. Patients with vaso-motor rhinitis and non-seasonal hay-fever are, in most cases, sensitive to food or animal emanation proteins.
4. Pre-seasonal treatment is the method of choice.
5. The intradermal is more reliable than the cutaneous method for testing sensitiveness. A 1:500 dilution extract was used.
6. Treatment has been with the acetone insoluble extract of the pollens.
7. It is fair to consider from the results obtained with the treatment of these patients that any patient correctly diagnosed as to the offending pollen and fully treated, receiving a maximum injection of 0.5 cc. of a 1:100 dilution of the pollen extract (1/200 gm.) can be assured of relief. In our largest number of cases, the fall hay-fever group, 82 per cent obtained over 75 per cent relief. Of this same group, 46.8 per cent were given over 90 per cent of relief.

A patient not sufficiently relieved by pre-seasonal treatment should be treated through the season, and the following year the patient should receive an increased amount of pollen extract.

SOME FEARS OF ENDOCRINE ORIGIN

By EDWARD HUNTINGTON WILLIAMS, M. D., *Los Angeles*

Whatever the mechanism involved in their production, the goal of what may be termed physical type of fears is the same, namely, the fear of death or bodily injury.

We are still in the stage of modified empiricism—of "scientific guessing," if you please—but a condition that frequently is the forerunner of actual scientific deduction and application.

DISCUSSION by Harold W. Wright, San Francisco; F. S. Marnell, Stockton; H. Lisser, San Francisco; Clifford A. Wright, Los Angeles.

IN OUR modern conception of the causes of disease, to speak of "endocrine" fears seems tautological, since fears, like the other emotions, are so intimately dependent upon the ductless glands. Moreover, the single word, "fear," is far too comprehensive a term, except as indicating a general group of conditions. For example, diffidence is undoubtedly a form of fear; so, also, is the sensation one experiences when his auto skids. The bashful boy is distressed and afraid in the presence of a single stranger, and he is afraid in the presence of impending death, as in the case of the skidding auto. But it is difficult to reconcile the idea that the same set of emotion-making anatomical structures are involved in producing these widely divergent sensations. Probably the same set of structures are involved, but all of them cannot be involved to the same degree in each instance.

I think we have very precise evidence of this in certain cases of morbid fears in which the state of the blood pressure is a symptom. We have the high tension, fearful misgivings of certain individuals, and the low-tension, depressed forebodings of another type. Both of these individuals are correctly referred to as fearful and afraid, according to our present conceptions. Indeed, their ultimate mental reactions may be almost identical. Yet it is highly improbable that the mechanisms producing these reactions are the same.

It may be pointed out that, whatever the mechanisms involved in their production, the goal of what may be termed physical type of fears is the same, namely: the fear of death or bodily injury. Such is not the case with the bashful or diffident. Often it is not the case in persons who have a fear of open spaces or closed-in places, or a hundred other morbid fears, which really do not threaten or portend death or bodily pain, and which the afflicted person may recognize as having no such import. And yet these sensations obtrude themselves, even though ruled out by reason. In such cases, it seems to me, a very different gland mechanism is at work from these cases where there is a normal fear of an actual danger. It is almost self-evident. But in most cases of this kind it is not always possible to put our finger on the exact location of the focus of the trouble, although our recent advances in endocrine knowledge is an earnest that presently we shall be.

I have had under observation and treatment for some little time several patients whose symptoms and response to treatment suggest that the cause of their fears is of pituitary origin—or, at least, that they are not the type of fears that one expects from

adrenal origin. Let us consider for a moment the sort of thing an adrenal disturbance stirs up.

We are all familiar with the action of adrenin when injected into the blood, as described by Cannon and others, that is, dilation of the pupils, erection of the hairs, constriction of the blood-vessels, inhibition of the activities of the alimentary canal, and the liberation of sugar from the liver. Also, there is likely to be paleness, trembling, twitching of the lips and gasping for breath, with changes in the blood pressure.

This composite gives us the classical picture, as well as the physical and chemical indications, of fear in which the adrenals are dominantly involved, either as cause or effect. It is the picture of fear as the term is applied ordinarily, an actual fear of definite bodily injury. Perhaps it would be permissible to call it the carnal type of fear, a kind that characterizes the fear in the lower animals and about the only one that such animals ever experience. It is a terror in which the emotion of indefinite worry plays no part: there is actual, tangible danger, not merely an indefinite, imaginary one.

In contrast to this type of fear, which seems caused or accompanied by pretty definite endocrine reactions, is the morbid, indefinite type of worry about, and fear of, some intangible thing, that can be explained away by scientific or common-sense deduction. Yet reason does not dispel it, at least more than temporarily. A little jest in one of the humorous magazines, a short time ago, suggests the type of thing I have in mind. The jest in question is this:

Two girls, sisters, in their early twenties, are strolling along the street. One sister is the phlegmatic type, the other sister thin and nervous, the typical worrying kind. As they walk aimlessly along, the thin sister says, mournfully:

"Oh, dear! I'm just worried to death about something."

The phlegmatic sister, surfeited with these perennial worries, replies somewhat petulantly: "Well, for heaven's sake! What in the world are you worried about *now*?"

The thin sister hesitates a moment, and then replies sheepishly: "Why—er—for the life of me I can't remember."

Now, this case, which is really authentic, although used as magazine copy, portrays a type of worry, or fear, if you please, with which we are all familiar. We see patients repeatedly who experience this vague apprehension, a fear and dread of a mysterious, impending danger, but an emotion so indefinite that they admit readily "there isn't really anything to worry about or be afraid of."

To me, such cases suggest an endocrine disturbance—are really cases of endocrine fears, as I am using the term here—but probably not the kind of fear that can be attributed to adrenal malfunctioning. Frequently, the characteristic adrenal symptoms are lacking, and in addition there are positive symptoms that point rather definitely to disturbances in other glands, such as the pituitary.

I am fully aware, of course, that in referring symptoms to this or that specific endocrine gland

action, I am taking liberties with our present knowledge of these glands. However, there are certain clinical symptoms and therapeutic reactions which seem to confirm our present conception of the action of some of these glands; and a certain number of patients receive benefit by treatment based on this conception. We are still in the stage of modified empiricism—of "scientific guessing," if you please—but a condition that frequently is the forerunner of actual scientific deduction and application.

I wish to give briefly the history of a case which, from clinical evidence at least, seems to bear out the idea that her fear symptoms were not those of adrenal disturbance primarily, and whose condition was definitely improved by treatment directed to some of the other endocrine glands. The case is one of a highly intelligent, cultured, and educated woman, now 57 years old. Her family history is negative, except that her mother was a rather timid and nervous type of woman. Her menstrual periods began at thirteen, were rather painful, but otherwise normal. She was of medium size, but well developed. She was always sensitive, rather timid, but not unusually so. Her first break came when she was 18. It was rather a mild depression, with headaches of a boring character in the top and anterior part of the head, which came on suddenly at irregular intervals, continued for a few hours, and stopped rather abruptly. Ordinary remedies did not affect them.

Mentally, she was depressed and somewhat irritable during these attacks, whereas ordinarily she was cheerful and exceptionally placid in her mental attitude. Her chief source of worry at this time was that she would not be able to accomplish certain things, some of them trivial in character, such as getting her dresses ready for a journey, or even doing the necessary shopping to get the dresses. This condition persisted for about three months, gradually disappearing, finally leaving her in a somewhat exalted state.

Following this first attack she had repetitions at intervals of not more than two years, each attack lasting from three to six months. All were very similar to the first one, although later in life they became more severe in character. In none of them, however, was she actually insane or obliged to be confined for treatment.

She married at twenty-five, and although her marriage was a happy one, and she naturally being very affectionate, she was frigid sexually. She became pregnant three years later, and her only child, a girl, is a robustly normal and delightful woman. Her husband is the stable, affectionately devoted type that must inevitably influence for the better any morbid condition of the purely mental type—that is, if there really is any such thing.

Yet none of these things—her married life, pregnancy, or menopause, which began at forty-five and was completed without apparent change or discomfort—seemed to influence her attacks of apprehensive and delusional depression. There was this modification when she was about thirty-five, however, namely: an increase in the severity of her headaches. Frequently, the headaches would waken her at night and last for several hours. At about this time there

was an increased tendency to hairy growth on the upper lip and chin. She was always myopic, but without astigmatism, and she wore properly adjusted glasses.

Between the age of fifty and fifty-three she had six attacks, lasting an average of five months each, the attacks coming on very gradually. In one of these, the second before the last, and the first in which I ever attended her, the delusional character of her fears bordered very closely on actual insanity. Thus, she heard workmen in the basement, was fearful that they were making preparations to harm her, and found great difficulty in reasoning this idea out of her mind. Also, in her last three attacks she developed an abnormal fear of death—an emotion entirely at variance with her normal attitude.

In addition to her peculiar and abnormal fears, there were certain and pretty constant symptoms that suggested pituitary, thyroid, and perhaps ovarian disturbance, rather than much disturbance of the adrenals. At least this was the impression of Clifford Wright, after considering these symptoms. Thus, there was an easy fatigability, such as we see often in asthenic cases with low blood pressure; yet her blood pressure was always normal, from 140 to 145 systolic. She lacked the power of sustained effort, particularly during the attacks. The masculine type of hair on the face in this otherwise delicate and effeminate woman, and sexual frigidity, suggests sex gland disturbance with pituitary trouble. And, also, the boring, explosive type of headache not dependent upon any gastro-intestinal condition or eyestrain, was a hint that the difficulty might be pituitary.

In this connection the nature of her obsessions—her fears—suggested pituitary trouble of a chronic nature, if the theory is correct that misfits between the gland and its fossa result in "compulsions, obsessions, and lack of inhibition." And, anyhow, we had presented a case that gave at least a strongly suggestive picture of fears of endocrine origin. Moreover, since no other forms of treatment had proved of any particular benefit heretofore, it seemed worth while trying the experiment of attempting treatment along the lines suggested by the possible endocrine involvement. She was, therefore, given a combination of ovarian substance and thyroid by mouth, and antuitrin hypodermically.

This treatment was started just at the time that one of her attacks seemed imminent. She was showing the mental symptoms that heretofore had never failed to herald an attack, particularly the fear about her wearing apparel, which in her case was pathognomonic. She was also having the characteristic headaches daily, but at irregular intervals.

Within a week after treatment was started, her headaches had become less frequent and much less severe. She was less depressed and much less fearful. And before the end of the first month it was evident that the attack had been aborted—or, at least, she had no headaches, none of the characteristic fears, and less fatigability—was, in fact, in a normal state of health physically and mentally. A week before that time the ovarian and thyroid treatment had been stopped, but the antuitrin was continued for two more weeks, a total of six weeks.

It has now been three years since she has had a fully developed attack, by far the longest period she has ever had since her first girlhood experience. During these three years, however, she has had four periods when there was a return of the headaches and the fears, but which were dispelled almost at once by a modification of the first treatment. In these later attacks the antuitrin was pushed to a greater extent, since that seemed to act almost as a specific in controlling the headaches.

Now, I am fully aware that one case does not prove anything to any degree of certainty—the woman was approaching an age when her attacks were likely to cease anyhow. But I have observed closely similar symptoms in younger persons that also responded to this type of treatment. More important for our purpose here, however, is the fact that the fear symptoms of these cases seemed to be definitely of endocrine origin, not purely "psychic," as had been diagnosed repeatedly.

Here is another case, seen in consultation with Dr. Ernest Bryant Hoag, of quite a different general character, but in which, as in the one just cited, the dominant mental symptom was a morbid fear. This case is a young man, now twenty-three years old. He is six feet three inches tall, rather slender, but well proportioned. Until his fifteenth year he was an unusually bright and active boy and of average size for his age. Beginning with that year, however, and without any discoverable cause, he grew seven inches in eight months, and has grown very little since then. His most rapid growth during that period was one inch in three weeks. Toward the close of this period he had several fainting spells, and many other attacks of protracted weakness. His mother reports that at that time his physicians put the patient to bed for four months on account of some heart difficulty, probably myocarditis with enlargement.

His heart is normal at present, systolic blood pressure between 118 and 124, pulse rate between 90 and 100. He attempted school after recovering from his heart difficulty and, although bright in his studies, he became exhausted so easily and so profoundly that he had to give up attendance, but continued his studies at home. He has very great mechanical ingenuity, is an omnivorous reader of good literature of all kinds, and is industrious most of the time.

His muscular tone appears good; but he has periods of great weakness, which is about his only abnormal physical symptom. His chief complaint is an all-defined fear that something will happen to him if he leaves the house or goes out into crowds, as on the streets. The very thought of going out on the street brings on this weakness.

By this time I feel sure that every physician here has drawn a perfectly characteristic mental picture of this boy—the psychoneurasthenic type that any trained observer can diagnose almost at sight, and whose personality is rated by neighbors and friends somewhere between "queer fish" to "plain crazy." But here is the surprising thing: This boy is not insane, not erratic, not even "queer." He appears, talks, and acts in a perfectly normal manner, although physically he seems to have the weakness of a person convalescing from a recent illness.

As to his morbid fears, he recognizes fully that they are purely imaginary—knows that there is nothing really for him to fear. And it is not timidity in the sense of diffidence, as he mingles and talks with the guests at his home. Yet this dread of the indefinable something, which he realizes does not actually exist, is such that he cannot overcome it to the extent of venturing far from his home.

It seems to me, therefore, considering the history of this case, that there is an endocrine basis for this young man's emotional state, which, for want of a better term, we call "fear." He is under treatment at present along the lines suggested by this conception, but sufficient time has not elapsed as yet to draw any definite conclusions.

Let me say, as a closing word, that I realize fully the inadequacy and dearth of really scientific data in considering my present subject. I surely do not intend to convey the impression that there is anything final or conclusive presented here, but rather some desultory observations about an interesting subject that I hope may incite enlightening discussion.

Pacific Mutual Building.

DISCUSSION

HAROLD W. WRIGHT, M. D. (Flood Building, San Francisco)—The two cases reported by Doctor Williams are of considerable interest and arouse speculations which could lead to nothing but difference of opinion. But these two case reports do not seem to be at all convincing on the side of the author's thesis. The relation between fear and certain rather vague endocrinopathic physical signs and symptoms is not very clear in either of the reports. In the first case, particularly, one is struck with familiar psychological signposts of an early acquired phychoneurosis which in its more acute phases bordered on a manic depressive psychosis and one cannot read this report without wondering how much more might have been learned by a more complete life history of the patient; certainly her fears were specific enough to be interpreted as symbolic of some definite mental complex. In some of the more modern psychiatric hospitals where there is enthusiasm for clinical research from every point of view many cases of apparently unwarrantable fears, as well as other psychotic symptoms, have been satisfactorily explained after the recovery of the patient on purely psychological grounds and have been shown to be due to an attempt by the patient to overcome or get around difficulties in personal adaptations to the environment, the psychosis being a way out of such. For example see Strecher's report of twenty recovered patients in the American Journal of Psychiatry for April, 1924.

In the second case reported by Williams attention is called to the fact that the fear of going out on the street succeeded a period in which the patient had had fainting attacks which were said to be due to an actual cardiac deficiency. May the subsequent fear not have been more likely due to suggestion instilled at that time?

As to the relation of emotions, such as fear to glandular activities, much work has been done by Crile, Cannon and others and their reports tend to confirm the belief that glandular dysfunctions are the result of fear and not vice versa. While it is true that we see emotional effects in one direction or the other in cases of hyperthyroidism or myxoedema, in hypo-pituitarism also, it is also true that we see many patients with such glandular disorders who are not emotionally affected thereby to any unusual degree. *In any neuropsychiatric disturbance there may exist several coincidental conditions and we need to be ever mindful of giving every factor consideration, but at the same time careful to estimate the personality as a whole.*

F. S. MARNELL, M. D. (Stockton State Hospital, Stockton)—The two interesting cases presented by Doctor Williams are of a nature to arouse considerable discussion. Both appear to be of the neurotic type of mental leaners, who always find some excuse to develop their

psychotic tendency. Freud explains them one way; Cotton gave them a physical base, now the trend is toward gland defects. *My experience with gland therapy leads me to believe, except in a few well recognized types, that the mind controls the glands more than the glands control the mind.* Most types of neurosis react well to any method of treatment that builds them up physically and leads their minds away from themselves. The woman acts like a neurotic of the self-protective class, who, when relieved of her menstrual and sexual stress by the menopause, reacted to the necessary mental suggestion accompanying her treatment. I believe the doctor gives too much credit to the medicine and not enough to his skillful handling of her mental processes.

The young man has a definite phobia with an explainable cause: The fear developed during his heart trouble led to a fear of being away from home and those who might secure aid for him in another attack.

In trying to explain the mechanism of the milder type of mental disturbance we are more inclined to look for something mysterious, than to give sufficient value to our ability to help the patient to reason correctly. A placebo is a wonderful remedy if we believe in it and transfer that belief to the patient.

H. LISSER, M. D. (Fitzhugh Building, San Francisco)—Whether one is inclined to agree or disagree with Doctor Williams' theory of the endocrine origin of fears, I gladly admit a genuine pleasure from the perusal of his paper. Not all of us possess a similar gift for expressing strange and novel thoughts in as pleasing and graceful a manner. Moreover he has disarmed some of the criticism that is the invariable lot of the pioneer, by modestly and frankly admitting that adequate scientific proof of his contention is not yet available, nor probably will be for a considerable time, if ever. However, it would seem to me unwise to dismiss his theory abruptly, quite as much so as it would be to gulp it down eagerly. In other words, the attitude of Mendel appeals to me—that of "the prepared open mind," which, in the present state of our knowledge, forbids either the rejection or acceptance of the author's theory. *A cynical intolerance is no more constructive than an ignorant credulity, and we have had too much of both in endocrinology.*

For my part, I confess to finding Doctor Williams' ideas rather intriguing, perhaps because I could duplicate his experiences many times, but have never dared to present them formally, perhaps for fear of ridicule. The rather magical relief of emotional disturbances coincidentally with the improvement of an endocrine disorder makes the conclusion somewhat tempting that the one is related to the other. It is, indeed, a difficult matter to prove, except in outspoken cases. No one will contest that the melancholia, emotional lethargy and mental torpor associated with myxedema may be relieved by thyroid extract, and that the emotional agitation, phobias and even mania of exophthalmic goiter may disappear through Lugol's solution and thyroidectomy. But the milder forms of ductless gland disease are not readily diagnosed with assurance and the same uncertainty applies to some of the disturbances in the realm of psychiatry. At least Doctor Williams' approach to their solution is more pleasing than some of the psychiatric dissections that expose an emotional interior as revolting as some of the findings at autopsy.

CLIFFORD A. WRIGHT, M. D. (2417 South Hope Street, Los Angeles)—This paper of Doctor Williams, as well as several others he has written on this subject, are of special interest to me, for I have had the opportunity of seeing some of his patients. He has been one of the first to attach due importance to the definite relationship between neuro-psychiatry and the study of the endocrines. His deductions are surely no less plausible than many we are expected to believe in regard to mental complexes, personal adaptations, etc.

The ground has been pretty thoroughly covered, but to reiterate—we are all well acquainted with certain fears and other nervous phenomena in some of the endocrine types of individuals. Like Doctor Lissier, we have not reported some of these cases, "perhaps for fear of ridicule." We have all observed the morbid, depressed, mental reactions of the hypothyroid and the excitable, even manic, state of mind of many patients with

exophthalmic goiter, and recognize them when we see them. No less certain, however, are many of the mental reactions that we see in pituitary types, and one of the most frequent conditions at the menopause is depression with uncertain phobias or fears. In some of these cases the disappearance of nervous phenomena can only be accounted for by the administration of glandular products—and it is no more unusual to see these patients greatly benefited than it is to see other normal reactions, such as we see in the effeminate boy with Froelich's syndrome—who will not take his own part and who does not have the proper attitude toward his fellow students—completely changed by the proper pituitary therapy. One case which I had under treatment—a married woman—would always (about ten days after her period) be wakened out of a sound sleep at night with a terrible spell of fear; she would rise from her bed and rush from her room into the open, temporarily losing control of herself. This was diagnosed under the head of so-called "Epileptic Equivalent," and while not relieved by the use of luminal, was relieved by luminal and ovarian products.

Briefly, I might call attention to three patients—two pituitary and one a combination of thyroid and gonad insufficiency. One of the pituitary patients was afraid that he was going insane and had carefully studied the matter out. Another had indefinite fears, being afraid to ride in a street car, or an elevator, or being where there were crowds of people. Both of these patients were relieved by treatment. The other, a successful wholesale man, was afraid to drive his car alone; to play golf. He would frequently go to the door of a prospective customer and be compelled to turn around and leave. He had dry skin, poor nails, constipation, and other symptoms of hypothyroidism and a definite history of loss of sexual activity.

It seems that this, and other works by Doctor Williams, are steps in the right direction.

LIPIODOL IN THE DIAGNOSIS OF CHEST DISEASE

By HOWARD E. RUGGLES, M. D., and LLOYD BRYAN, M. D.,
San Francisco

DISCUSSION by *Clain F. Gelston, San Francisco, and Harold Brunn, San Francisco.*

THE value of lipiodol in the diagnosis of inflammatory processes in the lung was first demonstrated by Sergent and Cottenot. They found that intratracheal injections of this fluid were harmless and gave beautiful casts of the bronchial tree. Other workers have extended the application of this procedure to a variety of chest conditions in adults and children.

There are two methods of injection. In one, a large curved trocar is introduced through the cricothyroid membrane under local anesthesia and the oil injected through it into the trachea. The second consists of cocainization of the larynx and the introduction of the solution into the trachea under direct observation. In our experience, the latter is the more satisfactory method. It is quickly accomplished, can be done in the office, the average patient is perfectly comfortable, there is little tendency to cough and the material is easily retained for a length of time, permitting adequate observation in several positions. In one instance, the introduction of 30 cc. of the oil was watched under the fluoroscope. With the patient upright, the bronchi of both lower lobes were completely filled before coughing began, and afterward he was watched in prone, supine and lateral positions, in an effort to outline a possible

cavity in an upper lobe, without discomfort or marked cough reflex.

Laryngologists prefer to inject patients in the upright position, with the result that only the lower bronchi are visualized. The material is heavy, as it consists of 40 per cent iodine in a vegetable oil and so drops directly into the most dependent portions of the lung. Most bronchiectatic cavities and bronchial dilatations occur at the bases and are, therefore, easily outlined. Lesions in the upper lobes are filled with difficulty. If possible the patient should be so placed that the suspected area is below the level of the trachea and the injection made slowly in this position. When only small amounts of the oil are used (under 30 cc.) in a single, continuous injection, one portion of a lobe may receive it all and when once placed it does not tend to spread throughout adjacent areas, but is gradually coughed up through the bronchi. Multiple injections and the use of larger quantities tend to equalize its distribution. Thirty to forty cubic centimeters are necessary for adequate visualization in adults. It is a good plan to turn the patient from side to side, and stand him upon his head over a chair or bed in an effort to drain the lesion before attempting to fill it.

In the normal individual the fluid gives a thin coating to the larger bronchi, and in filling the smaller ones produces a diffuse, flocculent shadow which is characteristic. Dilated bronchi are obvious, and the multiple grape-like masses in small bronchiectatic cavities are easily recognized. This is particularly valuable in lesions of the left base behind the heart and diaphragm, which are rarely seen in routine chest films.

The iodine remains in the cavities for long periods. Considerable amounts have been observed several months after injection, and it is still a matter of earnest discussion as to how much direct therapeutic effect may result from this iodization. No untoward effects have been noted following any of the injections. It might be supposed that persons susceptible to iodine would develop reactions to the considerable amounts some of them swallow in the process of clearing their bronchial tracts, but so far none have been reported.

The supply of the oil has been exhausted, due to a government ban upon its importation, apparently upon the ground that it is misbranded. Further work will depend upon renewed importations or the development of a similar product by an American firm.

Although Sergent warns against the injection of tuberculous patients because of the chance of producing congestion and reactions, it would seem that careful trials of the method in selected cases might lead to the perfection of a technic which would be safe and perhaps of value in diagnosis and therapy.

135 Stockton street.

DISCUSSION

CLAIN F. GELSTON, M. D. (380 Post Street, San Francisco)—I have naturally been much interested in the use of iodinated oil in investigating the bronchial tree in children since my work with Armand-Delille in Paris, who had applied the methods of Sergent and Cottenot. The opportunities offered seem to me not to be confined entirely to those cases of gross pathology, although, naturally, these are the most spectacular, and, of course, of

a great deal of value from the standpoint of lung surgery.

Should it ever be possible, however, to procure the necessary subjects, a most valuable contribution would be given to the study of the bronchial tree in the low grade chronic respiratory infections of both children and adults. In many cases these are, unquestionably, to my mind, accompanied by a certain degree of bronchiectasis, probably of the cylindrical variety. Should this investigation be possible, the work of Tallermann of St. Louis on the etiological relationship of lung fibrosis to bronchiectasis would be proven.

In the hands of the French observers, the route through the crico-thyroid membrane was found more feasible in children than the transglottic.

We are all pleased to learn recently that a substitute for lipiodol, and one equally satisfactory, is now on the market, so that these extremely important investigatory methods need not be given up.

HAROLD BRUNN, M.D. (384 Post Street, San Francisco)—I have been very much interested in the use of lipiodol in chest conditions from the time that Doctor Gelston returned from Europe with this method from the clinic of Arnaud-Delille.

As soon as we could obtain the lipiodol we immediately began using it in our chest cases for diagnostic purposes. At first we used the cannula method. This method is done as follows: A point over the crico-thyroid membrane is chosen and cocaineized with 1 per cent novocain. A small curved cannula made for the purpose is passed through the crico-thyroid membrane into the trachea. This can be done quite painlessly. The trocar is then removed and about 5 cc. of 1 per cent of novocain is slowly injected into the trachea in order to counteract irritation. Following this, the lipiodol, warmed so that it will run more freely, is very slowly injected into the trachea.

It is well to lay the patient on the side which it is desired to inject, although both sides can be done at the same sitting very frequently. We soon found that at first we used too small an amount of lipiodol, and latterly it has been our habit to use about 10 cc. first, then to wheel the patient into the x-ray room, having everything ready to take a picture, and inject 20 cc. more, taking the picture immediately thereafter before the patient begins to cough. Some patients are much more easily controlled in this than others. In some it is quite difficult to prevent coughing at the crucial moment. This usually spreads the lipiodol as a flocculi throughout the bronchi.

Lately, through the assistance of Herbert Cohn at the San Francisco Hospital and Carson Martin at the University of California Hospital, we have been able to get wonderful pictures by having the substance dropped through the larynx after complete cocaineization. We have found the greatest use of the method in our work in the diagnosis of bronchiectasis.

Before the injection it is well to have the patient empty his lungs by turning him upside down. The same holds good of lung abscesses but these are seldom visualized with the lipiodol. For some reason it seems quite difficult to get the lipiodol to enter a lung abscess cavity. We have had several cases of bronchiectasis on the left side in which the x-ray, before injection, appeared quite normal, but which came out very beautifully after the injection, showing fingerlike cavities behind the heart. In none of the cases that we have used it has there been any symptoms of iodism or any untoward result. In one of my cases in which I performed a lobectomy of the lower lobe for bronchiectasis the lipiodol still remains in the other part of the lung, now a period of six months.

I consider the method practically harmless and a great help in the diagnosis of certain lung conditions.

Students Work for Education—Of the 10,000 students who are in attendance at the University of California this year, 7500 must aid themselves financially by securing work of some sort, according to Mrs. Leslie W. Ganyard, manager of the Alumni Bureau of Occupations, who says her organization expects to be called upon by 1500 or 2000 of these students for assistance in securing work to defray at least a part of their college expenses.

THE RELATIONSHIP OF METABOLIC TOXINS TO DERMATOSES

By O. V. SCHROETER, M. D., Los Angeles

As dermatologists, we have seemed to be much more concerned with skin pictures, with variations of skin pictures and with dermatologic symptomatology and pathology, than with the mysterious perpetrators of cutaneous injury.

We must seek out the site of toxin formation, the conditions under which toxins are formed, their intimate character, and their effect at the site of deposition.

There is a mutual interdependence of microbic nutrition and potential microbic action. The food of the host is an important factor both in controlling the kinds of bacteria that multiply in the intestinal canal and in determining the nature of the products these bacteria form while they are resident therein.

DISCUSSION by Samuel Ayres, Los Angeles; Anstruther Davidson, Los Angeles; Harry E. Alderson, San Francisco.

IN A RECENT paper I sketched skeletally the pathology of toxic dermatoses. I endeavored to show therein that there are different degrees of toxic action which are expressed in different degrees of pathology on the skin surface, that this toxic action finds its expression through the capillaries, and I indicated that the etiology of this condition was toxin carried in the blood stream.

It has been my effort here to seek what light we now have on the metabolic origin of these toxins, their character, their insignificance or importance with relation to the causation of the urticarias, erythemas, and purpuras. It is surprising that so little has been done in the way of clinical research into the etiology of these diseases of the skin. As dermatologists, we have seemed to be much more concerned with skin pictures, with variations of skin pictures, and with dermatologic symptomatology and pathology rather than with the mysterious perpetrators of cutaneous injury.

The study of such a problem concerns branches of the broad field of medicine rather foreign to dermatology itself. We must seek out the site of toxin formation, the conditions under which toxins are formed, their intimate character, and their effect at the site of deposition. In all this we have isolated facts, and we have hypotheses; from them we must gather such knowledge as we can, with a view to a better understanding and care of the toxic dermatoses.

Of course, I am here assuming only the area of metabolic activity in the etiology. I feel sure my assumption is well founded. The first and most logical place of introduction of intracorporeal toxins is the alimentary tract, and years before the day of bacteriology proper, scientists studied the question of alimentary toxemia. Outstanding among these is Bouchard, who made numerous experiments, in an endeavor to accurately incriminate secretions and excretions and faulty metabolism in the production of certain symptom complexes. He might be aptly called the "father of auto-intoxication." Conditions in the bowel are admittedly favorable for the production of decomposition products and for the production of pathological biological chemic substances. We might conceive the production of these to be based on faulty digestion of foods or upon the action of certain elements of the intestinal flora upon

foods; the latter outweighs the former greatly from a pathological point of view. As we study the various phases of these processes of enteric bacterial life and faulty metabolism, certain definite biological and chemical facts emerge.

Arthur Kendall has studied the biochemistry of the microbes themselves. It is analogous to that of living matter anywhere. Protein is the substance to which all else is added in life and upon and within which the vital story of life plays itself. Nucleoproteins are chemically prominent in the bacterial substance. The specific protein of all living things is a multitudinous combination of amino acids, of which some twenty are now known. These are acids in which one H atom is replaced by the radical NH_2 . With the exception of nitrogen-fixing microbes and nitrifying organisms, the bacteria of the bowel (as elsewhere) require, or utilize more readily, amino N for their structural needs. Nitrogen must be present for their biologic requirements; N, in fact, is the very cornerstone of life. A series of H condensations in which amino acids or complexes thereof, together with carbon, hydrogen, oxygen, and inorganic salts are woven into protoplasm. From this living material must the toxins of organic life be produced. For microbial catabolism, there are two great energy-containing substances available in the food of the host—carbohydrates and proteids. There is oxidizable C contained in each, but the substances resulting from the intracellular vital combustion of this carbon may be widely different. The same organism may produce harmful or harmless substances as it uses the carbon of carbohydrate or of proteid (peptone). Again, different bacteria produce different toxins on the same media; for instance, the diphtheria bacillus on peptone and meat extractives forms the diphtheria toxin, and the bacillus coli produces indol thereon. If ordinary glucose is added to the media before inoculation, the diphtheria bacillus produces lactic acid and not the toxin and in place of the indol, the colon bacillus produces acidic products, mostly lactic acid. This without any structural change in the microbes.

There is a mutual interdependence of microbial nutrition and potential microbial action. The food of the host is an important factor both in controlling the kinds of bacteria that multiply in the intestinal canal and in determining the nature of the products these bacteria form while they are resident therein. Undesirable microbial activity may be of at least two types:

1. Causing harmful protein derivatives, as in putrefaction.
2. Causing irritant acidic substances, as in fermentation, such as butyric, lactic and acetic acids in unusual quantities. As to the difference in putrefaction and fermentation, we will leave this matter as irrelevant here.

Thus, as curative measures, dietary regulation and the deliberate introduction of bacteria inimical to the growth of harmful types have been introduced.

The study of the chemistry of bacterial metabolism—true of cellular metabolism in general—is in its formative state; it must await the development of new chemical methods. Complete analyses of pro-

tein materials always leave a very wide margin of unknown amino acids.

We have considered the products of the growth of intestinal bacteria in a general way. Before taking up the next step, the ingesta, as a source of toxin, bound up with this bacterial growth, permit a few words with reference to the bile. My experience would give decided importance to the deleterious effects on the skin of bile retention. I vividly recall an elderly patient who came with a cutaneous disturbance, much resembling a chronic scabies—skin scars were very numerous from seven years of scratching, and the skin showed many papules and scratch-marks. About the time I had uncovered the hepatic area as guilty, the patient took to her bed with acute cholecystitis, whereupon the skin cleared as if by magic and the itching ceased. Pruritus is, often enough, the only manifestation of a low-grade toxemia, transitory or persistent. Bouchard showed that bile itself is about six times as toxic as urine, but that, while at first the cholates salts were suspected, it was found that the biliary coloring matter was the important toxic agent and that the intoxication arose from the setting free of toxic substances which entered into the composition of the cellular elements. It should not be forgotten, however, that we have also a deficient splitting of the fats due to absence of bile in the duodenum. This causes an intensification, it has been supposed, of the putrefaction in the large bowel, and even already in the small intestine. Pancreatic juice has been shown by Müller to have little effect on the digestion and absorption of fats. What is really important, however, in this bile deficiency is the fact that the fats, not being properly split, digested, expose the bowel to the effect and the system thus, to the absorption of acrid butyric and other fatty acids. And it has been contended by good authority that it is this, and not putrefaction proper, that particularly gives the offensive odor to the stools in such cases.

The intestinal secretion is an alkaline liquid which has a fermentative effect on carbohydrates and aids the pancreatic secretion in converting starches into sugar. Disaccharides are converted into absorbable monosaccharids. It has been shown by experiment that digestion can be carried on in the bowel in the absence of most of all of the secretions and bile. Bacteria supply the deficiency. The direct products of abnormal carbohydrate fermentation are acetic, formic, propionic, butyric, valerianic, lactic, and succinic acids. The presence of such or their products in the blood conceivably act as irritant capillary poisons.

It is, however, the proteids that play the important role in the metabolic toxemia of the toxic dermatoses. The small intestine, and particularly the large intestine, are capable of passing the products of putrefaction into the blood. There has been much controversy, however, since the day of Bouchard as to how harmful these may be and as to what disposition is actually made of them by the tissues. As stated, in considering bacillary metabolism, so, of course, is it true that the amino acids are the integral feature of proteid food as of protoplasmic chemistry. The waste products produced by the combustion of the proteids are much more difficult to dispose of than those of the sugars,

starches, and fats. And we are now particularly concerned with the metabolic protein toxin, whether of bacillary or digestive origin and its effect, than any classification of its method of production. Perverted nutrition may conceivably lead to the development of new substances which may be toxic. Bouchard, in 1882, showed the presence in feces of the alkaloids of putrefaction, and Brieger, in 1883, showed that such alkaloids may be formed during the act of peptonization. It has been shown that an aqueous extract of putrid matter is very toxic, and that of fecal matter slightly so; the alcoholic extract of putrid matter, however, is not very toxic, but that of fecal matter is decidedly so. The amins are formed from ammonia by replacing H with an alcohol radicle, which might explain the toxicity of alcoholic fecal extract. Since Bouchard, many experiments have been done in an endeavor to clarify the question of auto-intoxication. While putrefaction plays a part in the toxicity of feces, it is less than often supposed. We can conceive it as an indisputable fact that certain toxins can be and are developed in the intestinal tract, that they are a result of fermentative and putrefactive processes on carbohydrates and proteins, and that, from a toxic standpoint, the latter are the most important. What these toxins are, we have indicated. Since the products skatol and indol have been proven of questionable importance in auto-intoxication, renewed interest has followed the demonstration that certain of the amino acids derived from the breaking down of proteins are able to furnish exceedingly toxic amins by the removal of one CO_2 complex. In this way, from tyrosin, a crystallizable amino acid, there is produced tyramin; from tryptophan, indolethylamin and from histidin, a decomposition product of the protamin of sturgeon testes, histamin, the latter all very poisonous. The chronic injection of these has been shown by Harvey to produce serious symptoms. Some of these products have been formed by the activity of bacteria derived from the feces, and some have been found under special circumstances in the intestines.

Facing, then, the question of metabolic toxemia squarely, conceding here and denying there the result of experiment or clinical incrimination of certain discoverable entities, and admitting a certain proven, or, as yet undeniable residue, these complex products, the first-born of a new and more wonderful chemistry admittedly, then, swept into the vital circulation, what is the last link in the chain of phenomena that inscribes on the skin the wheal of urticaria, the rosy patch of toxic erythema, the varied picture of eryth. multiforme or the alarming extravasations of the purpuras?

I have reiteratingly mentioned the capillary as the end-station of toxemia and the basis of dermic pathology of this type. H. H. Dale of London, in an admirable article, states that the capillaries, with their intimate relation to and constant chemical interchange with the tissues, must be especially exposed to any influence on the vascular tonus which the products of metabolism may exert. CO_2 , credited with a potent vaso-dilator action, has not been demonstrated to have a pronounced effect on capillary tonus. Taking histamin, a poisonous product of protein decomposition just mentioned, Dale has

shown that it has a potent toxic action on the capillary in very great dilution, causing loss of tonus and exudation. He has further shown that this toxic effect on the capillary has been nullified or much mitigated if the animal is previously given an injection of adrenalin. In short, it has been found that histamin, by experiment too, and adrenalin are antagonistic to each other. Pituitrin had a similar action.

So here again we are dragged back to the glorious contemplation of the combat and defense between the poison of organic life and the forces of the living organism contained in the blood. Is it not a fair conclusion, then, when we see adrenalin, the vital extract of a living organ, injected into the circulation, nullifying the effect of a poison derived from the decomposition of organic vital matter, is it not, I say, a fair conclusion to maintain that an overdose of a proteid amino acid or amin in the circulation, or the want of proper hormone in the circulating cases, permits the phenomena of the toxic dermatoses by allowing the effect of such a toxin on the capillary wall? And is it not a further fair conclusion that our treatment of these cases should be in the administration of proper dosage of these hormones as well as in combating the source of the condition in the body? The logic of this is already strikingly shown in the beneficial effect of adrenalin in cases of urticaria.

Plain muscle contraction and loss of capillary tonus occurs as the central feature in the action of a large class of protein poisons. These poisons must have their usual origin in the alimentary tract. In addition, there are possible acidic, irritative poisons, the product of fermentation. The effect of the protein poisons has been shown to be effectively combated by certain hormones, particularly adrenalin and pituitrin, which are derived from glands of internal secretion and, therefore, normally supplied the circulation in health. Insufficient amount of hormone, or overdose of protein or acidic toxin not destroyed by the beneficent action of the liver, results in the deposition of the toxin in the cutaneous termini of the circulation, the capillaries, producing the lesions of the toxic dermatoses.

DISCUSSION

SAMUEL AYRES, JR., M. D. (Westlake Professional Building, Los Angeles)—Doctor Schroeter deserves credit for directing the attention of dermatologists to some of the recent contributions of biochemistry. Of course, we all know perfectly well that we should keep our minds focused on the etiological factors of skin disorders, but it is so easy to settle down into the false security of complicated nomenclature and to feel that we have performed our full duty when we have made a careful diagnosis.

Pronouncing a diagnosis on any one of the numerous members of the toxic dermatosis group is only the most elementary step in handling the individual patient. The cause, even though often undeterminable, should be searched for diligently and every new advance in biochemistry or internal medicine which has any bearing on the subject should be enlisted. Modern medicine no longer tolerates the mere treating of symptoms and most of the toxic dermatoses are nothing but cutaneous symptoms. Symptoms must be relieved as an incidental procedure, but the main attack should be aimed at the underlying derangement, to restore normal function and to prevent recurrences.

A recent valuable contribution which Schroeter did

not mention was the work of Alvarez and confirmed by Donaldson, who showed that all the symptoms of auto-intoxication, such as headache, delayed reaction time to touch, sight and hearing, increased basal metabolism, increased blood sugar, increased neuromuscular fatigue, elevated blood pressure, may all be produced by mechanical distention of the lower bowel, entirely independently of toxic absorption. Packing the rectum with cotton pledgets in a group of individuals experimentally substantiated the hypothesis. This does not prove that the absorption of the toxic products of putrefaction or fermentation may not also lead to derangements of function. Presumably the distention of the bowel operates through the involuntary nervous system in producing its effects.

ANSTRUTHER DAVIDSON, M. D. (419 South Alvarado Street, Los Angeles)—The author's desire to elucidate the influence of metabolic disturbances on the skin is rather timely, as the tendency at present is to ascribe the majority of the cases of dermatitis to local or extraneous causes.

Doctor Schroeter has, I think, unduly stressed protein poison as a causative factor. While affections like urticaria are the local expression of an acute anaphylaxis as T. B. and syphilis are examples of chronic anaphylaxis due to a protein poison, many of the affections such as eczema and acne are probably chemical, rather than protein in origin. The rash that follows acetanilid and other chemicals is caused by the chemical forming with the colloids insoluble products. In eczema and acne the chemical products resulting from errors in carbohydrate metabolism are probably the chief factors.

There is not at present sufficient evidence to convict the bacteria of the intestines of playing an important part in the causation of skin diseases. The presence or absence of certain forms is so manifestly dependent on "soil conditions" that their influence can only be of secondary importance.

HARRY E. ALDERSON, M. D. (240 Stockton Street, San Francisco)—From a purely clinical standpoint it has been recognized for years that various dermatoses, particularly those mentioned by Schroeter, are due to so-called toxins. These diseases have been treated more or less empirically, but with the idea of eliminating those mysterious toxins, with considerable success. Biological chemistry is now clarifying the situation and placing therapy in many of these troubles on a more scientific basis.

The relationship of impaired liver functions to cutaneous disturbances has been recognized for years. Intense itching, associated with even very slight icterus, is a common occurrence. Similar phenomena in connection with abdominal malignancy are likewise well known. We appear to be on the threshold of discoveries that may explain more definitely the mechanism or some of these processes. As Schroeter states, there are many chemical products resulting from the breaking down of foods or bacteria which are capable of producing cutaneous symptoms. These symptoms may be manifested in the form of a frank eruption, or the skin may show increased vulnerability. There occur alleged "occupational dermatoses" which are due principally to these causes. Altered functions of various internal organs may be responsible for the breaking down of proteins and formation of toxins. Disturbed thyroid activities, and functional disturbances of other ductless glands in many cases constitute the main etiological factors. And so it may be said that the dermatologist, to be really successful, must be, at all times, an internist.

DOCTOR SCHROETER (closing)—I want to emphasize that toxic dermatoses, of course, must, in their last analysis, be the result of toxins and toxins are chemical, whether bacterially produced in the throat, as in scarlet fever, in the bowels, or introduced by ingestion like acetanilid. All toxic dermatoses have characteristics which stamp them as such to every dermatologist, and whether produced by drugs or an undetected internal factor, they all have a striking resemblance in basic character. While the group of toxic dermatoses have, of course, been long recognized as a group of skin diseases, yet the specific production and modus operandi of the toxins have been hitherto, and are still, dark in many particulars. It has been my poor effort here to submit something more definite as to these matters and to incite more interest in the chemical and laboratory study of these toxins and their action.

MASTOID SURGERY *

By CULLEN F. WELTY, M. D., San Francisco

I believe that indications for and the type of operation for chronic suppuration may be selected as clearly in the near future as we today differentiate in findings and methods between the acute and the radical operations.

A patient who has had the radical mastoid operation needs attention three or four times a year as long as he lives. Without such attention, trouble will follow and, if neglected too long, reoperation may be necessary.

DISCUSSION by John LaRue Robinson, Reno, Nevada; D. H. Townbridge, Fresno; J. W. Green, Vallejo.

BECAUSE of the many different operative procedures devised for acute and chronic suppuration of the mastoid process, it might be in keeping to tell you what I have been doing for some ten years past. Various operations have been tried; different dressings, as well as the technique of the operations.

Probably the individual surgeon will have better success with his own technique. There are many ways in which failure can come. So when I go into detail, it is absolutely necessary for you to carry out in detail everything that I may say. A part cannot be selected and another discarded, for I am going to make some very striking statements and, in a way, hold myself responsible for your performance, provided you fulfil the instructions.

To make this a little more striking, I am going to say that I have not lost a patient following an acute mastoid operation during a period of fifteen years, either in my city and county hospital service or among my own private patients. Many times my patients were not selected by myself, but were forced upon me because of the position I occupied.

In an acute otitis with temperature, tenderness and increased white blood count following an incision of the drum membrane, with increasing difficulties and a decided bulging of the posterior superior wall (the most reliable symptom of all), something must be done to relieve the pent-up pus. The interval that may be covered by such a process of reasoning is from three days to two weeks.

If at the end of two weeks or later there is a pulsation of the pus through the perforation, without any other symptom, the surgeon may be perfectly sure that he will find pus in the mastoid. If at the end of two weeks, or later, there is bulging of the posterior superior wall, without any other symptoms whatsoever, it is certain that the mastoid is full of pus. Facial paralysis is always an indication for immediate operation during the course of an acute otitis, and there are many other conditions quite familiar to all ear surgeons that should be considered to be clear indications for operative interference.

A condition that stands out alone in diagnostic value and was called attention to by me fifteen years ago, is that an acute otitis should not be allowed to exist for a period of more than six weeks without operation because the hearing is so likely to be impaired, or a permanent perforation remain that will be an annoyance for the balance of the individual's life. I consider it criticizable negligence to allow an acute otitis to become chronic, and I be-

*Read at the Annual Session of the Nevada Medical Association, Reno, September, 1924.

lieve the time will come when medical authorities will so consider it. In hesitating about doing an unnecessary operation, it is well for the surgeon to bear in mind that a good surgeon will not damage a healthy ear, but by delay every now and then a patient will be lost.

The indications for the acute mastoid operation are based largely upon clinical symptoms and history, coupled with a few definite findings. If a patient suffering from an acute mastoiditis does not improve steadily from day to day, surgical interference is positively indicated. This holds good any time, from the third day to the fourteenth day of the disease; after that the patient belongs in another class to be judged in another way. My technique for the acute mastoid operation contemplates the removal of every individual cell. Every cell that can be found with an instrument I call a searcher (not as large as the end of a pin) is removed until hard bone is encountered everywhere. The attic is opened freely and all cancellous bone removed from this area.

When every individual cell has been removed with a hand burr, chisel or other instrument, the cavity is packed with plain gauze. The ear is packed with plain gauze; a few stitches are taken at the angle and the head bandaged. An ice-cap is applied constantly to the operated ear for twenty-four hours and the wound is dressed in four days, provided everything remains satisfactory. Should the patient have fever following operation, such as I have described, one of three conditions are present in order of frequency—remaining cells carrying infection, beginning of an acute infectious disease, or cerebral complication, the most frequent of which is thrombosis of the lateral sinus.

Under favorable conditions it will be found that the discharge from the ear has ceased entirely at the first dressing. Loose packing is then reinserted in the ear; gauze is removed from the wound and loose gauze is inserted; gauze fluff is added and bandage again applied for two days, when the second dressing is done. The wound should continue to be dressed every second day, so long as it remains free from pus. As soon as pus appears it is dressed daily until it is again free from pus. In the event of oversized granulations developing, they are removed with a small curret, or cut down with nitrate of silver fused upon a probe and the silver neutralized with salt solution. If granulations fail to develop, a thick pack of iodoform gauze is inserted; changed daily until the granulations are normal, and then the part dressed with plain gauze. During the past ten years, under such treatment I have never found it necessary to reoperate a single, individual case in a series of about four hundred cases. (As this paper is about to go to print, I have had to reoperate one of my acute cases. The detailed history of this case would be too complicated to go into at this particular time.)

The radical mastoid operation I believe has come to stay. I do not see how it can be improved upon. However, I do not believe that every case of chronic suppuration of the middle ear (chronic after one year), especially in children, should have the radical mastoid operation.

Some ten years ago I did the acute mastoid opera-

tion in a series of twelve cases with chronic suppuration of the middle ear. Many cases were excluded. The only cases that were accepted were free from vertigo, tinnitus, headache, cholesteatoma, facial paralysis, and free from disease of the promontory or attic wall.

In this series all recovered but one, and it was found at the second operation that he had cholesteatoma. This must have been overlooked at my examination or at operation, or it was so small at the time that it was not seen. Ever since that time I have been using the same reasoning in deciding the kind of operative procedure in given cases for children (up to 12 years of age).

Certain operations for chronic suppuration of the middle ear impress the surgeon by their results, and I am not so sure but what in carefully selected cases, such as I have spoken of before in children, some adults might be successfully treated by surgery. I believe that indications for and the type of operation for chronic suppuration may be selected as clearly in the near future as we today differentiate in findings and methods between the acute and the radical operations.

When we differentiate between the various operative measures for the cure of chronic suppuration of the middle ear, some few lesions stand out alone and cannot be cured by any other procedure than the radical mastoid operation. These include cholesteatoma, facial paralysis, caries of the promontory, caries of the attic wall inside or outside, vertigo or any cerebral or cerebellar symptoms. The operation must remove the lesion; nothing short of that will suffice. This, I believe, will become the accepted condition governing operative procedures for chronic suppuration of the middle ear. Furthermore, I expect to see the gradual disappearance of chronic suppuration of the middle ear by the improvements that have been brought about in the preliminary care of acute otitis and mastoiditis. I am not going to enter into a discussion of the indications for the radical mastoid operation, because we have specific indications established by most of the textbooks of otology. The only cases warranting disagreement are those in which a specific indication does not exist. I refer to the cases that have a chronic discharge from the ear and do not have other symptoms or demonstrable lesions. Some of these patients are cured by treatment, but they do not remain cured. Probably 5 per cent of the cases cured without operation remain well. So, after trying for a short time to bring about a successful issue, I am ready to recommend the radical mastoid operation, or one of the surgical procedures for the cure of chronic suppuration. For these patients (who comprise the great majority) have been very satisfactory in every way. Among this class of patients I have never had one regret the operation. I am more enthusiastic about the radical mastoid operation than ever before.

I do not believe I have had more than four or six patients who were not cured. However, a patient who has had the radical mastoid operation needs attention three or four times a year as long as he lives. Without such attention trouble will follow, and if neglected too long reoperation may be necessary.

By the use of the graft described by me some ten years ago, the whole of the after treatment is very much simplified; the hearing is better and the patients make a much quicker recovery. It may be possible that the resistance to debris is not so good. However, it is a question. I have lost four patients of approximately six hundred operated upon—one from brain abscess and three from purulent meningitis.

210 Post Street.

DISCUSSION

JOHN LARUE ROBINSON, M. D. (Reno, Nevada)—Doctor Welty was made an honorary member of this Society in 1904; I think the first honorary member of the Society. He has contributed much to our enjoyment and enlightenment during the past twenty years, and we always appreciate his contributions.

The doctor's paper just read, I think, expresses the advanced thought of today upon the subject. The one point, however, I would like to touch upon is the method of dressing. For several years I have used a perforated rubber drainage tube in lieu of gauze, because: It seems to me more humane; my cases have dried in much shorter time; we have less scarring.

Recently, I had a paralysis of the right rectus following an acute mastoid operation, which gave me considerable concern. I sought, in vain, help from every angle possible for an explanation. In relating the circumstance to Doctor Welty, he immediately suggested that it might be "Gradinigo's Syndrome," which was reported in *Laryngoscopy*, 1924. I now believe that my patient belonged in that classification.

Welty speaks positively concerning the proper procedure in chronic suppuration of the middle ear, and I am inclined to believe that most of us come to the same conclusion after years of experience.

D. H. TROWBRIDGE, M. D. (Fresno)—I wish to congratulate Doctor Welty on a very complete and interesting paper in which I agree almost entirely. He has expressed my ideas almost exactly as regards the treatment of mastoid infections, and I agree heartily with him on his line of treatment. Particularly, I agree with him in not neglecting to operate upon an ear that has been discharging for four or five weeks, which, having been properly treated, refuses to heal at the end of that time. I think it was Dench who claimed that any ear that discharged for two weeks had involvement of the mastoid. I would not say that every ear in which the discharge does not cease in four or five weeks would not eventually get well, but I do feel that any patient with an ear that has discharged for four or five weeks is much safer with a simple mastoid operation than to have it left in a discharging condition. Not only safer as a matter of life and death, but much more likely to have good hearing than if allowed to discharge for several weeks longer, even if at the end of that period the ear has become perfectly dry, as it will also be more or less permanently deaf.

There is very little danger from a simple mastoid operation if done by a skillful surgeon. On the other hand there is certainly much danger in waiting indefinitely since almost every year aurists of large experience observe several cases of meningitis which rapidly succumb. These fatalities could be avoided, as Welty points out, by early operation.

In my experience of about eight hundred mastoid operations, I cannot recall any bad results from any simple mastoid operation. Like Welty, I can say I have never lost a patient as a result of simple mastoid operation, but I have lost patients where the operation was complicated by meningitis or brain abscess that had already begun before I operated, and I have come to feel that one is hardly justified in operating upon mastoids where meningitis is already established, even although it is very slight. The only reason I would operate in a case of this kind is that occasionally in children where meningitis apparently exists, the symptoms have cleared up following operation. To illustrate, during the past winter a woman suffering from considerable pain was referred by her family physician to an aurist who did not con-

sider the fact that her ear had been discharging for six weeks, or that she was suffering severe pain over that side of her head, sufficient to indicate mastoid involvement, since there was no tenderness on pressure over the mastoid, and even in the face of the severe pain and chronic discharge he neglected to operate. About five weeks later the patient was sent to me, but at the time I saw her the woman had a well-marked meningitis and soon succumbed to the disease. I am satisfied that an early simple mastoid operation would certainly have saved her life.

I wish to accentuate Welty's statement concerning thoroughness of operation. Every mastoid cell, whether diseased or healthy, should be removed if possible. Theoretically a perfect mastoid operation is one in which all of the cells are destroyed and the contents of the mastoid bone removed down to the inner table. If this is accomplished, the condition clears up earlier, healing is more rapid and there are fewer recurrences.

A case in point is one in which I did a radical operation this past winter, on a patient who had had a simple operation by an aurist about a year previously. Upon opening the mastoid cavity I discovered that only about one-half of the cells had been removed at the previous operation. This patient had suffered intense pain for several months as well as complete loss of hearing because he had had an incomplete simple operation, whereas a complete removal of all of the mastoid cells would have saved his hearing entirely and effected a cure at the time.

For the last four or five years I have ceased to use the gauze pack. After the first dressing, which is usually on the third day, I insert into the wound a specially selected, thin-walled, soft rubber drain of pure gum. This has a large caliber almost one-quarter of an inch in diameter and is inserted well upon to the top of the wound and is made shorter from time to time as the wound heals. In some cases I have been able to remove the drain within two weeks, others require a longer time. I am satisfied that this method of dressing is practically painless and I am equally sure it shortens the period of healing very markedly.

In conclusion, it is my opinion that if we have more simple mastoid operations, in a few years we will have very few radical mastoid operations to do.

J. W. GREEN, M. D. (Vallejo)—Doctor Welty has covered the ground of mastoid surgery in a more able manner than I could present it, but, I believe, he has omitted a most important detail when he fails to mention x-ray studies of his operative mastoids. In my own practice this is a routine part of examination in all cases where it is possible to obtain good pictures. I know that it is not absolutely necessary in making a diagnosis of mastoiditis and neither is it absolutely necessary to have this information in all cases to help determine when to operate; but I have seen two cases in which there was no discharge from the middle ear at any time and no mastoid tenderness or swelling which would help one to arrive at a diagnosis. One of these had been diagnosed typhoid fever and the other incipient tuberculosis. The x-ray is just as important as the laboratory findings in these cases. So much for its help in the unusual cases.

Concerning the ordinary case: A good x-ray tells you the comparative size of the mastoid cells, whether or not there is a marked process and great breaking down of the cell walls, whether there is anomalous placing of mastoid cells (such as extension toward the occiput). A study of both the normal side and that which is diseased will tell you (because in health, both sides develop exactly alike unless there has been previous inflammation) whether there is sinus thrombosis, peri-sinus abscess, subdural abscess and in many cases brain abscess. One is, occasionally surprised to note the enormous size of the mastoid in young children. All this information is of immense value prior to the operation.

It is a fact that early operation will prevent the serious complications and a good surgeon will not injure an ear, even if he should operate in a case which would have recovered without operation, but I have found it wise to operate only and when my best judgment advised me to do so. Every surgeon of experience has this additional sense of intuition. Procrastination has no place in mastoid surgery.

Discharge from an acute otitis media, which does not cease within two weeks after free paracentesis, gives me great concern, as there is one of two conditions present in these cases, mastoiditis or granulations within the middle ear cavity, or both. In all these cases a simple mastoid operation is indicated.

Complete removal of all mastoid cells invariably results in a cure, and I have used a different method of closing the wound and dressing than the one recommended by Welty for the past five years. I close the wound with clips or silk worm and place a cigarette drain of small size directly into and by the shortest route to the mastoid antrum. The wound is allowed to fill with blood prior to suturing. The drain is removed on the third day and many of these wounds heal in ten days or two weeks. This method has been termed the "blood clot" operation. This operation has been successful many times, even in the presence of a demonstrated "hemolytic streptococcus infection."

I am not so enthusiastic concerning the radical mastoid operation. Many chronic otitis cases may be cured by the simple mastoid technique. Perseverance with local treatment will, many times, cure a long established chronic otitis media.

In closing my discussion, to return to the matter of the x-ray, the picture is valuable only as the experience of the interpreter is based upon correlation of the findings at the operating table and the reading of the actual anatomy shown.

THE CALIFORNIA STATUTE AUTHORIZING THE COURT'S EXPERT: ITS HISTORY AND FUNCTION

By ANDREW STEWART LOBINGIER, M. D., Los Angeles

INTRODUCTORY NOTE

Doctor Andrew Stewart Lobingier, serving as chairman of the Medico-Legal Committee of the California Medical Association and the Los Angeles County Medical Association, has led the forces of medicine for sixteen years, in efforts to bring about improvement in our laws governing medical expert evidence.

California now has a new law that gives promise of better things. Doctor Lobingier and Mr. Oscar Mueller, representing the Bar Association, who worked with the medical committee, are jubilant over the passage of the new law.

In transmitting the story of the long fight and a copy of the new law, published below, Doctor Lobingier writes:

"We are the first state in the Union to have achieved this legislation, and I think you will pardon me if I seem a bit enthusiastic over it.

"We are so proud of our victory that Mr. Mueller has proposed that we make an effort to interest the bar and medical associations of a number of Eastern states in the passing of similar legislation.

"I have made the report you requested as succinct as was consistent with the record, and would appreciate a prominent insertion in California and Western Medicine, with editorial comment from yourself, which I feel certain will be commendatory."

While not perfect, this law is the best that could be gotten, even with the active participation of the League for the Conservation of Public Health. It is a step in the right direction, and if courts, attorneys, and physicians will co-operate in its enforcement, disheartening and reprehensible scenes, which have too frequently characterized the administration of justice, will become less frequent.—
EDITOR.

SIXTEEN years ago, on motion of the writer, the Los Angeles County Medical Association voted to request the council of the association to appoint a committee to confer with the committee on New Legislation of the Los Angeles Bar Association and act jointly with it in proposing an Act which should regulate the giving of expert evidence.

It was believed by this joint committee that a bill

could be framed which would, to a great extent, correct the evils which have rendered the giving of expert testimony in our courts humiliating and worthless.

As chairman of the Medical Committee, the writer was invited to deliver an address on Medical Expert Testimony at a dinner given by the Bar Association to the Justices of the Supreme Court of California on the evening of October 15, 1909. The address was published in the Southern California Practitioner and in the California State Medical Journal.

The argument set forth that the expert witness, as usually called by plaintiff or defendant, became a biased advocate for the side which employed him. That our system of taking expert evidence was archaic, expensive, and obstructive of the ends of justice.

In certain foreign countries the expert witness was selected by the court and thereby became an officer of the court, and was chosen from the most competent and accomplished representatives of a given profession. The testimony of such a witness, answerable to neither side, but only to the high court which called him, was characterized by sincerity, dignity and fairness, free from bias or prejudice and, as far as could be, was a dispassionate statement of scientific fact.

Repeated efforts had been made in the various commonwealths of the republic to have enacted statutes which would in some such manner clothe the expert witness with authority and freedom which would facilitate the giving of such scientific testimony without prejudice to either side, a candid statement of scientific truth without bias. All such efforts had, and have until this time, proved futile. Certain members of the Bar, certain corporations which had a singularly obtuse slant on the merits of this legislation and, strange to say, certain presumably scientific members of the learned professions interested, opposed the enactment of any such statute. The result has been a long, stubbornly contested effort for more than twenty years in America, with final defeat in every instance except our own.

The first bill drafted by our joint committee and presented for passage in 1911 had reference only to the giving of medical expert testimony.

It was rejected by the Legislature because it was said to be class legislation and should have regulated the giving of all expert testimony of whatever kind.

A new bill was then drafted governing the giving of expert testimony of every profession or business and presented to the Legislature in 1913. It passed the Senate and failed in the House, owing to the vast number of bills at that time before the Lower House. The same bill was presented in 1915, passed both Houses, and was vetoed by the Governor. As this same executive was continued in office for another term, and as he was known to be unfriendly to such an Act, we concluded not to present the bill again as long as he was in office. The war then intervened and our interests and energies were elsewhere engaged. In 1921 the same bill was again presented, passed both Houses, and was again vetoed, but by another executive, who admitted "he had no personal objection to the bill, but

had been advised by certain attorneys that it was undesirable legislation."

Nothing was done thereafter until this year—1925. Mr. Oscar Mueller, representing the Los Angeles Bar Association, had been with me most actively in all our efforts to get this bill enacted into law. Mr. A. H. Koebig, representing the Society of Engineers; Dr. Thomas J. Orbison and Judge Frank Oster had also given sympathetic and valuable assistance.

In 1914, Mr. Mueller and I, at our own expense, visited various cities of the state and made addresses before bar and medical associations in behalf of this legislation. On invitation, we addressed a joint meeting of the San Francisco Bar and Medical Association. From time to time we made reports as chairmen of our several committees to our local and state associations. This year we determined to make one final effort to secure the passage and executive approval of the bill. Senator Jones of San Jose, always a loyal and indefatigable worker for the bill, did the most to make possible its passage in the Senate. At one time it was tabled in the Judiciary Committee of the House and seemed destined to fail of passage, but it was finally taken up and put through. Letters favoring its passage were written by university presidents and justices of the Supreme, Appellate, and Superior Courts, and sent to Sacramento. When Governor Richardson signed this bill he was kind enough to say publicly, "he considered it one of the best enactments of this Legislature."

What will be the effect of the statute in facilitating and dignifying the giving of expert testimony in the courts of California?

1. It will greatly reduce the number of experts called in a case and have thus a distinct economic value.

2. It will facilitate and expedite the trial of a case when the court calls its own expert.

3. It will dignify expert evidence, for the court's expert is an officer of the court and free from prejudice for or against plaintiff or defendant.

4. It does not invade the right or privilege of plaintiff and defendant calling their own experts.

5. It secures the expert of the court at a reasonable and just compensation, shared by the litigants and the state.

Finally, for eight or ten years Superior Judges of this city have, with consent of opposing counsel, called the court's expert with the greatest satisfaction to all and to very great economic advantage. So that long before the Act passed into law, the courts here had abundantly proved its practical value by showing its reasonable and just merits in the trial of their civil and criminal cases.

Recently, in the criminal case of the People vs. Young, the court called two alienists to pass upon the sanity of the defendant. The result of this first instance of record where the statute providing for the court's expert has been put into effect will be awaited with much interest.

Merritt Building.

THE NEW LAW

An Act to amend the Code of Civil Procedure of California by adding thereto a new section to be numbered and known as Section 1871, relating to experts, their appointment by the court, or a judge thereof, and provid-

ing for their compensation and manner of examination as witnesses.

The people of the State of California do enact as follows:

Section 1. A new section is hereby added to the Code of Civil Procedure of California, to be numbered and known as Section 1871, and to read as follows:

— Whenever it shall be made to appear to any court or judge thereof, either before or during the trial of any action or proceeding, civil or criminal, pending before such court, that expert evidence is, or will be required by the court or any party to such action or proceeding, such court or judge may, on motion of any party, or on motion of such court or judge, appoint one or more experts to investigate and testify at the trial of such action or proceeding relative to the matter or matters as to which such expert evidence is, or will be required, and such court or judge may fix the compensation of such expert or experts for such services, if any, as such expert or experts may have rendered, in addition to his or their services as a witness or witnesses, at such amount or amounts as to the court or judge may seem reasonable. In all criminal actions and proceedings, such compensation so fixed shall be a charge against the county in which such action or proceeding is pending and shall be paid out of the treasury of such county on order of the court or judge. In all civil actions and proceedings such compensation shall, in the first instance, be apportioned and charged to the several parties in such proportion as the court or judge may determine and may thereafter be taxed and allowed in like manner as other costs. Nothing contained in this section shall be deemed or construed so as to prevent any party to any action or proceeding from producing other expert evidence as to such matter or matters; but where other expert witnesses are called by a party to an action or proceeding they shall be entitled to the ordinary witness fees only, and such witness fees shall be taxed and allowed in like manner as other witness fees. Any expert, so appointed by the court, may be called and examined as a witness by any party to such an action or proceeding or by the court itself, but when called shall be subject to examination and objection as to his competency and qualification as an expert witness and as to his bias.

Such expert, though called and examined by the court, may be cross-examined by the several parties to the action or proceeding in such order as the court may direct. When such witness is called and examined by the court, the several parties shall have the same right to object to the questions asked and the evidence adduced as though such witness were called and examined by an adverse party.

The court or judge may at any time before the trial or during the trial limit the number of expert witnesses to be called by any party.

THE PRE-OPERATIVE PREPARATION AND SURGICAL TREATMENT OF CHRONIC SPLENIC ANEMIA (BANTI'S DISEASE)

By LEO PECCI BELL, M. D., *Woodland, California*

Splenic anemia patients, in a well-advanced state, should be splenectomized as soon as possible after careful preparation by transfusion and rest. If splenectomy is resorted to before an advanced degree of cirrhosis has taken place, complete and permanent cures are obtained. Great care should be observed not to operate in a state of acute thrombo-phlebitis with temperature.

WHEN discussing the function of the spleen and its diseases, I am reminded of the story W. J. Mayo so frequently tells of the professor who asked a student to describe the function of the spleen. He stammered and stuttered and finally said that he had known but had forgotten. Whereupon the professor replied: "I am sorry you have for-

gotten because you appear to be the only one who has ever known."

It is definitely known that the spleen and liver of the foetus are blood producers; the liver up to about the fourth month, the spleen up to the fifth month. But, before birth, they lose the power of producing red blood and the spleen becomes a destroyer of debilitated red cells. The spleen begins to show senile changes at puberty, and after this time is more likely to show pathologic change.

Anatomically, the spleen is closely associated with the foregut. Its blood supply, which comes from the celiac axis, is altogether too large for its own nutrition. Moreover, when the arteries enter the spleen they lose their outer coats and become sinuses in which only the endothelium lies between the splenic pulp and the vessels. The fact that the splenic veins do not primarily enter the general circulation but become part of the portal circulation suggests that, whatever may be the action of the spleen on the blood, it is not completed and the splenic blood must pass through the liver to be acted upon there before it can enter the general circulation.

The sympathetic nervous system provides a close network about the splenic artery and its branches, and this in turn connects with the solar plexus and so with the adrenal glands. The vagus enervates the muscle fibers in the connective tissue. There has been some experimental work on the possible relationship between the spleen and the thyroid and thymus glands, but it is not conclusive.

Gaskill has proven that the spleen has very little anatomic nerve supply and deduces from this fact that it has no important internal secretion, since all organs of internal secretion have an abundant anatomic nerve supply. As proof of lack of internal secretion the normal spleen can be removed without any apparent disturbance.

Splenic anemia was first described by Gretsels in reporting a case from the clinic of Professor Greisinger, who had recognized lymphatic anemia and splenic anemia, and who used these names in his clinical dissertations to distinguish them from a large group of pseudo-leukemias, so-called. Banti, by collecting the pathological studies of Lodi, Concato, and Franzoline and the clinical studies of Greisinger and Gretsels, and by his clinical observations and necropsy studies in three cases, further separated this disease from a large group of splenomegalies. By his description of a disease which has been given his name, Banti stimulated investigation of disease of the spleen and particularly of splenic anemia.

Osler classifies splenic anemia as a primary disease of the spleen of unknown origin. It is characterized by progressive enlargement. Attacks of anemia are accompanied by a tendency toward hemorrhage, small in some cases, and by a secondary cirrhosis of the liver, with jaundice and ascites. That the spleen itself is the seat of the disease is shown by the fact that complete recovery follows its removal.

Rolliston, discussing this group described by Osler as "Primary Splenomegaly With Anemia" under separate headings, "Chronic Splenic Anemia" and "Banti's Disease," says he considers chronic splenic anemia as presenting the following characteristics:

(1) Chronic splenomegaly, which cannot be correlated with any recognized cause; (2) the absence of enlargement of lymphatic glands; (3) chronic anemia with low color index; (4) the absence of leucocytosis and usually the presence of leukopenia; (5) the liability of copious gastro-intestinal hemorrhage from time to time; and (6) prolonged course without any tendency to spontaneous cure. Splenectomy is usually curative.

Rolliston, in discussing the relation between Banti's disease and splenic anemia, says: "The title Banti's Disease is now often used as synonymous with splenic anemia even by those who fully recognize that it is a sequel or terminal stage of splenic anemia, and does not occur in all cases even when unduly prolonged."

Rollins claims that Banti describes three stages of the disease named for him: (1) the preascitic stage in which splenic enlargement is present with or without anemia; (2) the transitional stage, of which the most prominent symptom is diarrhoea and at which time anemia and blood changes are found, the liver is somewhat enlarged and jaundice may be present; (3) the ascitic stage, or Banti's disease proper.

The normal function of the spleen is considered to be chiefly that of a mechanical filter, which removes from the blood degenerated red blood cells and toxic agents above colloid size, such as microorganisms and debris, on which it acts before sending them to the liver for further detoxication and elaboration. It also develops lymphocytes.

The spleen, when chronic splenic anemia develops, acts as a focus of infection, being a storehouse for infection whose toxic materials are dumped too rapidly into the liver, causing a cirrhosis to take place. It also undergoes changes of function which cause an overdestruction of red blood cells.

The relation of the spleen and liver in action has been compared to the glomeruli and tubuli of the kidneys, for the spleen extracts certain products which it passes on to the liver for disposal. This is true not only of waste products, but also of certain substances which the liver must return to the body to maintain normal life. With regard to the latter function, the spleen may be considered as a "scraping plant," where the worn-out blood cells are delivered to have removed from them whatever may be of further service to the body.

Gato, in animal experiments, found that the amount of pigment in the bile was relatively diminished after splenectomy, both with and without the administration of hemolytic agents.

The spleen assists in producing immunity. This is indicated by experiments in which Morris and Bullock have demonstrated that splenectomized rats were more susceptible to ordinary infections, and to sublethal injections of live bacteria, than were others on whom abdominal castration had been done for controls. It is well known that the spleen can filter parasites of disease from the blood, but it cannot destroy these organisms. Probably the most striking example of this is the accumulation of plasmodia of malaria, the ague-cake of the tropics. The same is true of the spirochaeta pallida. The enlargement of the spleen in typhoid fever and chronic infections is

due to the accumulation of bacteria and the reaction to infection.

The spleen apparently does not initiate the pathologic processes with which it is concerned, but acts as a secondary agent.

Thus the spleen in splenic anemia shows marked fibrosis, including thickening of the capsule and trabeculae and changes of a fibrotic nature in the reticula. Endophlebitis is also sometimes to be found. The spleen pulp itself is greatly increased in amount, chiefly due to increased number of venules. Wartkin believes that in many, if not in all, cases of splenic anemia the underlying condition is obstruction in the splenic and portal circulation most commonly due to thrombophlebitis. The action of the spleen normally may be likened to that of a filter, removing not only old red cells, but also bacteria from the circulating blood, and we must suppose the ordinary acute splenic tumor to be, in part at least, in connection with this function. If the splenomegaly is the result of the isolation of malarial organisms, or of tubercle bacilli or the spirochetæ of syphilis or other organisms, then we have a specific disease and we regard the enlargement of the spleen as merely one of the body protective measures. There must be, however, many similar splenic reactions against various bacteria or toxins. If this be pronounced, of fairly long standing, and accompanied by anemia of marked grade, we group the cases as splenic anemia or Banti's disease. This, at least, is the present status of the matter. This theory practically infers that the anemia is a secondary matter, and that the splenic enlargement is the primary thing. We could, of course, refer the anemia to hemorrhages, except for the fact that they are not constant and, in fact, are absent in some cases, showing very low red counts. The red cells of splenic anemia do not show an increased fragility. W. J. Mayo leans to the opinion that a fibrotic spleen destroys more red cells and that, in the absence of any special stimulation of the bone marrow, anemia must result. He suggests, too, that the disease changes may bring about reductions of the pigment production and thus actually reduce the hemoglobin balance.

In an exhaustive study, Krumbhaar considers that all diseases of the blood in which anemia is produced depend on the dynamic standpoint of the constant interplay of the blood-forming and blood-destroying apparatus, termed the hemolytopoietic system, and the adjustment there spoken of as the hemolytopoietic balance. The question, considered in regard to the anemia of splenic anemia, is whether this condition is due to an excess of blood-destruction or to a paucity of blood-formation. In considering the cause of the anemia the chief factors are the bone marrow, spleen, liver, lymph nodes and reticulo-endothelial apparatus. By the close inter-relation of this system and the taking over of the function of one by another in disease, Krumbhaar explained the rapidity with which the blood picture approaches the normal after splenectomy.

In the Bradshaw lecture for 1920, Sir Berkeley Moynihan draws attention to the fact that the spleen is not a specialized organ with one or two particularly developed functions, but is one of a group of organs more or less interdependent. Failure to recognize this is, perhaps, the chief reason

why the splenic functions have for so long remained obscure. Moynihan's conception of the problem is more illuminating, in that he considers the spleen to be closely connected with and, in fact, a part of four important systems of the body.

(1) *The spleen as a part of the hematopoietic or blood-making system.* Formation of red and white cells takes place in the spleen only during embryonic and early post-natal life, as a rule. In infections and leukemia, however, the spleen may take part in the production of white blood cells. The relation of the spleen to the bone marrow has already been discussed.

(2) *The spleen as a part of the reticuloendothelial system.* We have already described the endothelial cells as lying loosely in the reticulum of the spleen pulp. The liver also has certain large phagocytic cells, the star cells of Kupffer which are endothelial in nature. They are known to proliferate after removal of the spleen, and they may take up iron pigments. Lymphatic glands also contain phagocytic endothelial cells, which multiply after splenectomy. The bone marrow, too, contains somewhat similar cells. Thus, these structures seem definitely related morphologically, and we can more easily understand why blood pigment is found in the liver, lymph glands, and bone marrow when hemolyzing poisons are administered. It has been found, in studying the immature bodies of cholera, that the spleen and long bone marrow contains the largest proportions of these substances. Various other experiments on animals indicate that the spleen is an important power in resisting infective processes.

(3) *The spleen as a member of the digestive system.* All the blood of the spleen passes into the liver, carrying hemoglobin within the bodies of the wandering cells. The spleen, therefore, stands in an important relation to the liver. It is known, of course, that synchronous with digestion there is a slow expansion of the spleen, but what bearing this change may have upon so-called digestive leucocytosis is not clear. It is stated that splenic extracts cause intestinal peristalsis. A further connection with the digestive system lies in the probability that the spleen takes part in purin metabolism.

(4) *The spleen as a part of the sympathicoendocrine system.* It is assumed that the spleen has a sympathetical endocrine function, but it is impossible to prove it.

In a detailed resume, Connors considers cases of splenomegaly which may be classified from diagnostic standpoint into acute and chronic. I shall discuss here only chronic forms, the most important of which, from a differential standpoint, are myelogenous leukemia, lymphatic leukemia, Hodgkin's disease, chronic malaria, hemolytic jaundice, polycythemia-vera, pernicious anemia, Gaucher's disease, Von Jaksch's disease, syphilis (hereditary and acquired), tuberculosis, kala-azar, chronic infections, Still's disease, purpura, hepatic cirrhosis, obstruction to the portal vein, Amyloid disease, and tumors.

The diagnosis of splenic anemia depends on the existence of splenomegaly, varying degrees of anemia of the secondary type, usually leukopenia and a relative lymphocytosis, and the frequent occurrence of gastric and intestinal hemorrhages. Because of the hemorrhages, the condition is often diagnosed as gastric or duodenal ulcer, the splenic enlargement, even

though considerable, being overlooked or disregarded. It should be emphasized that in cases of gastric or intestinal hemorrhage, splenic anemia must be eliminated as a cause. In the later stages of the disease (Banti's disease) the existence of a very large spleen and ascites, due to the associated hepatic cirrhosis, together with the foregoing findings, usually suffice to make the diagnosis. Sometimes it will be impossible to separate the condition from primary hepatic cirrhosis with splenomegaly; the existence of a large liver and a comparatively small spleen or an atrophic liver with rather a small spleen, especially if ascites is present, favors a diagnosis of hepatic cirrhosis. Occasionally syphilis presents such a picture. Norris, Symmers, and Shapiro believe that all cases of so-called Banti's disease are due to syphilis.

The pathological findings and clinical records of sixty-nine patients with splenic anemia on whom splenectomy was performed at the Mayo Clinic from November 14, 1905, to September 1, 1920, were reviewed by Chaney in great detail. The most important points in his findings are as follows:

1. A composite picture of the pathological findings in the spleen in splenic anemia was found to be one of generalized fibrosis. There were no findings in the splenic tissue which would enable the pathologist to make a positive diagnosis of splenic anemia, yet the abnormality was as characteristic of this disease as in other diseases producing splenomegaly.

2. The average weight of the spleens was found to be 1015 gm.

3. The average age of the patients with splenic anemia was 33 years, and the number of males about equal to the number of females. There was apparently no familial tendency.

4. Their most common complaints were mass in the left abdomen, gastric hemorrhage, and weakness.

5. While abdominal pain was rarely given as the chief complaint, the histories brought out the fact that thirty-two of the patients had attacks at some state of the disease. In many instances the pain was probably due to perisplenitis.

6. In sixty-nine patients the average erythrocyte count was 3,700,000 Hg., 53 per cent; leucocyte count, 4990; coagulation time and the fragility tests were normal and the Wassermann tests and the stool examinations were negative.

7. A comparison of the number of lymphocytes in the differential count showed that the average was within the limits of normal. A lymphocytosis did not seem to be a characteristic in this series.

8. In the study of the liver tissue in the cases of splenic anemia, thirty showed a definite cirrhosis, but in none was the liver entirely normal.

9. Twenty-four of the patients with cirrhosis had ascites.

10. Twenty-three and three-tenths per cent of the patients with cirrhotic livers died within forty days of the operation, while within the same length of time the death rate of the remaining patients was only 12.8 per cent.

Zaccarelli, in 1549, and Ferrerius, in 1711, have been accredited, by some authors, with removal of the spleen, but these cases have been discredited by others for lack of sufficient detailed records. The

earliest authentic cases of splenectomy are those reported by Quittenbaum of Rostock in 1826, Kuchler of Dermstadt in 1855, and Spencer Wells of London in 1866, each reporting a case of splenectomy.

In each case the patient died a few hours after operation. Plan, in 1867, did the first successful splenectomy from which the patient recovered.

From Collier's table of twenty-nine cases of splenectomy reported from 1549 to 1881, we find a mortality rate of 72.4 per cent. Van Wert's thesis of 1897 records 274 cases with 104 deaths, or a mortality rate of 37.9 per cent.

Modern surgical methods and proper selection of cases have reduced the mortality in splenectomy from all causes. Giffen, in 1921, reported a series of seventy-three splenectomies for splenic anemia in which nine deaths are recorded, a mortality rate of 12.3 per cent.

To illustrate what has been accomplished by splenectomy in splenic anemia, I would like to cite three cases from our clinic which present the three types of cases described by Hollins.

During the last two and one-half years, six cases of splenic anemia have been encountered, illustrating the types of the disease, progress, and operative cures.

CASE REPORTS

Mr. E. W. Age 33. Superintendent Water Company. First observation on January 8, 1924.

Present Illness—Following a fall in December, 1919, patient was ill three days and complained of weakness. Following this he had a very severe hemorrhage, vomiting blood and also passing a considerable quantity by bowel. At this time he was confined to bed for fourteen days. X-ray diagnosis was negative. His second hemorrhage was in August, 1920, at which time he vomited blood and was in bed one week. In May, 1921, the third hemorrhage occurred. Fourth hemorrhage January 4, 1924, at which time the patient passed blood by bowel two days. Since the first hemorrhage, the patient has complained of weakness, but feels that this has not been progressive. No symptoms referable to ulcer. No genitourinary, cardio-respiratory, or sensory symptoms.

Physical Examination—General Appearance: Sallow and anemic. Throat: Infection of tonsils, second degree. Teeth: Dental sepsis, second degree. Blood pressure, 110/80. Abdomen: Slightly tender in upper left quadrant. Liver: Palpable; not markedly nodular. Spleen: Enlarged eight to ten times.

Temperature, pulse and respiration, normal.

Laboratory Findings—January 8, 1924, Hg., 42 per cent; r. b. c. 2,800,000; w. b. c. 4300; color index .7 plus; number cells counted 200; polys 48 per cent; small lymphs 31; large lymphs 16.5; large monos 2; transitional 2.5; slight anisocytosis; slight poikilocytosis; moderate polychromatophilia; coagulation time 6 minutes; fragility .28 per cent to .30 per cent increase in resistance. Blood Wassermann negative. Urinalysis negative.

On January 11, 1924, this patient was transfused with 450 cc. of blood, the indirect sodium citrate method being used, and six days later (Jan. 17, 1924) splenectomy was done. The following findings were made at operation: Stomach showed large vericosities over fundus and under pyloric end—no sign of ulceration of stomach. Liver showed little cirrhosis compared to average case of Banti's Disease. Gall-bladder was thick-walled, emptied easily and there were no stones. Spleen six to eight times normal size, with extensive adhesions over the surface, and was covered with thick plastic exudate of greyish color. The patient had an uneventful post-operative course and was dismissed on the fifteenth day post-operative in very good condition. By the first of March he felt very well and was allowed to resume light work. May 19, 1924, Hgb. 82 per cent, r. b. c. 5,140,000, condition excellent. Early in September, 1924,

the patient reported again for observation: hgb. 86 per cent; r. b. c. 4,650,000. Had resumed heavy work and felt himself entirely well. Very well at present time.

Mr. F. B. Laborer. Age 28.

Present Illness—Five years ago onset of present trouble began with a sudden attack of vomiting blood. Considered hemorrhage quite severe; was in the army and did not stop drill work. After this time felt fairly well until one year ago when he again had a severe hemorrhage from the stomach—this did not weaken him greatly. He felt normal after vomiting and continued to work. The third attack of vomiting was March 27, 1923; of the same nature and also passed blood by bowel; no marked weakness following this attack.

Physical Examination—Seems in good physical condition except for some pallor. Throat: tonsils atrophic. Abdomen: Spleen freely movable about 4 inches below costal margin. Liver enlarged about 4½ inches below costal margin. Blood pressure 165/90.

Laboratory Findings—March 29, 1924, Hgb. 45 per cent; r. b. c., 1,130,000; color index, 1.9 plus; w. b. c. 4400; 200 cells counted; small lymphs, 25.5; large lymphs, 2.5; large monos, 2; trans, 3; polys, 66.5; basophiles, .5; slight anisocytosis; moderate poikilocytosis; slight basophilic stippling; moderate polychromatophilia; bleeding time 10 minutes. March 29, 1924, transfusion of 400 cc. of citrated blood was given. April 3, 1924, w. b. c. 3400; Hgb. 50 per cent; r. b. c. 3,470,000. April 16, 1924, splenectomy done; liver markedly cirrhotic; spleen five times enlarged, plastic lymph exudate over entire surface. Marked vericosities over stomach and diaphragm; no free fluid. Usual splenectomy done.

Reaction following splenectomy excellent. Convalescence was entirely uneventful. Within two months, the patient was working again, and has had no trouble. Recent Hgb. is 75 per cent; r. b. c., 4,500,000. Has had one hemorrhage since July 1, 1924, by bowel, moderately severe. Apparently not affected by hemorrhage and working again, as before.

Mr. E. L. M. Age 29. Examination, October 30, 1922. Complaint: Weakness and loss of appetite.

Present Illness—About 7 years ago began to lose weight and have a feeling of dragging and loss of ambition, with marked weakness on exertion. Would gain weight for a time and feel better; later would lose again. Has grown slowly and progressively worse with greater loss of strength. Night sweats for six months; no temperature or chills. Bleeding from gums and nose. No vomiting of blood or passing blood by bowel. Has noted enlargement of abdomen for last two years.

Physical Examination—Poor physical condition; sallow and emaciated. Teeth: pyorrhoea and dental sepsis III. Spleen very large, extending to umbilicus, and quite painful. Abdomen distended to a moderate degree.

Laboratory Findings—October 23, 1922. Hgb. 44 per cent; r. b. c., 3,860,000; w. b. c., 14,200, group III. On admission malarial parasites were demonstrated. The patient was given a course of intravenous salvarsan and intravenous quinine with one course of Deep Therapy over the spleen, over a period of six weeks. The night sweats disappeared and he felt much better, but the spleen grew larger. No transfusion given.

Splenectomy on October 4, 1922. Spleen densely adherent to diaphragm and lateral wall and about ten times normal size. Usual technique of operation. Considerable hemorrhage. Liver markedly cirrhotic. No gallstones. For six months following operation, patient had to be tapped five times, but finally began to get better and has gradually improved in strength. Has been working as foreman on a ranch for the last year. July 18, 1924, white count 5600; 31 small lymphs; 4 per cent large lymphs; 62 per cent transitionals; Hgb. 80 per cent; r. b. c., 4,130,000. Very well at present time.

Mrs. J. E. K. Age 29. October 10, 1922.

Present Complaint—Rapid heart and weakness for about four years, with palpitation of heart, excitability, tremor of hands following exertion—all symptoms mild in degree. Marked loss of strength. About three years ago began to have enlargement of upper abdomen which continued for six to seven months and gradually receded.

Physical Examination—Teeth, marked dental sepsis.

Heart, moderate dilatation, systolic murmur over base and apex. Spleen enlarged three to four times. Considerable pallor.

Laboratory Examinations—Hgb., 23 per cent; r. b. c., 3,150,000; leucocytes, 4400; cells counted, 200; small lymphs, 23 per cent; large lymphs, 1.5 per cent; large monos, 2.5; trans, 4.0; polys, 68.0; eosin, .5; baso, .5; slight anisocytosis; moderate poikilocytosis; slight polychromatophilia. Urine examinations negative. The patient was given a transfusion of 500 cc. of citrated blood and advised to have all foci of infection removed as she had many bad teeth. Her tonsils were negative and there was no history of previous tonsillitis. Since this time the patient has improved very markedly in strength and activity. Has been kept on iron at intervals. Present Hgb., 72 per cent; r. b. c., 4,200,000; spleen and liver about comparable in size. Size of spleen has diminished until it is just palpable under the costal border. Blood picture about the same.

Miss H. S. Age 40. May 9, 1924.

Present Illness—January 11 began to have diffuse abdominal cramps and severe vomiting and chill; high white count 13,000; temperature 102. Operated elsewhere January 23, 1924; chronic appendix; liver and gall-bladder normal. Patient seemed to go into uremia afterward. April 2 had recovered sufficiently to be taken home. Hgb., 50 per cent. For two weeks stationary; some tendency to diarrhoea. April 28 some blood in vomitus; some acute pain in abdomen. On entry into hospital May 4, 1924, spleen was palpable 3 cm. below costal margin. Blood count: Hgb. 35 per cent; r. b. c., 2,410,000; slight poikilocytosis; moderate polychromatophilia; w. b. c., 6200; 200 cells counted; polys, 71.5; small lymphs, 21.5; large lymphs, 2.0; large monos, 2; trans, 2; eos, 1. Blood urea normal. P. S. T., normal. Transfusion of 500 cc. of citrated blood. Feces examination negative. Wassermann negative. Fragility increased. X-ray of chest negative. Since leaving the hospital has had a very severe hemorrhage with more transfusions. Was then diagnosed as toxic ulcer elsewhere. Has had two hemorrhages and two transfusions since leaving hospital. Blood shows same picture.

Miss H. G. Age 6. November 6, 1924.

Present Illness—April, 1923. At this time parents noted nose bleeds as often as four or five times in twenty-four hours. The child became languid and tired and did not wish to play with others, though she apparently had no particular weakness. Skin and whites of eyes, yellow.

The initial attack of jaundice lasted about two to three months. Since that time attacks of two to three days' duration every month or so. No pain at beginning of P. I., but shortly began to complain of severe colicky pain under umbilicus and the longer attacks of pain were usually associated with the jaundice mentioned. In addition many transient attacks of pain. Constant tenderness under umbilicus; occasional tenderness in pit of stomach. Vomited during early stages of this illness, with the attacks of pain and jaundice, but, during last eight months, has been nauseated with attacks without vomiting. Temperature ranging from 99½ to 101½, the latter being in August and September. Temperature rise usually in morning. Enlargement of the abdomen was first noted at the time of onset of the P. I.

Physical Examination—General Appearance: Child in good flesh and nutrition; seems somewhat anemic. Throat: Enlargement of tonsils with infection. Blood Pressure: Systolic 95; diastolic 50. Abdomen: When lying flat there is a definite enlargement of the upper left abdomen. On palpation spleen extends down to about 1½ inches above the umbilicus. Moves freely to about ½ in. of navel. Seems slightly tender to touch. Liver extends down about 1 to 1½ inches below costal margin. Slight tenderness below and around umbilicus. Temperature: Slight rise.

Laboratory Reports—Blood count; r. b. c. 3,450,000; Hgb. 65 per cent; color index .95; w. b. c., 3150; polys, 50 per cent; small monos, 49 per cent; large monos, 1 per cent. Blood examination: No parasites found. Slight anisocytosis, moderate poikilocytosis. Reticulated cells, 0.6 per cent. Myelocytes, none found. Urinalysis negative. Feces examination, negative. Urine examination for bile,

negative. Blood Wassermann, negative. Fragility test: Complete hemolysis, .32 per cent (NaCl); beginning hemolysis, .42 per cent (NaCl).

Diagnosis—Banti's disease (splenic anemia) chronic appendicitis. Immediate operation recommended, but, to date has not been performed. Child to return in March for splenectomy.

In considering this group of splenic anemias, it should be borne constantly in mind that the basic pathology of the spleen is generalized thrombophlebitis, resulting in secondary anemia, the initial onset coming as an acute thrombo-phlebitis, following most commonly influenza, or follicular tonsillitis. The probable bacteria is the streptococcus, which has a particular attraction for lymphoid tissue. Many spleens are found enlarged in influenza if a careful examination is made in severe cases. The fact that all individuals who have respiratory infections do not develop splenic anemia is due to resistance of the individual to streptococcus infections. The streptococcus, incysted in lymphoid tissue following an attack of follicular tonsillitis may result in rheumatism and endocarditis. Thus, when in an individual with lowered resistance the spleen is infected and repeatedly fed with more bacteria which it constantly strains out from the blood, fibrotic changes are initiated and the spleen itself becomes a focus of infection, the excess blood destruction probably being a toxic action from bacterial growth within the spleen. When these toxins, generated by the spleen, are poured into the liver, parenchyma cell destruction of the liver takes place and the destroyed parenchyma tissue is replaced by fibrous tissue. As the anemia becomes pronounced, the fibrosis and liver destruction increase until the ratio of liver destruction exceeds liver regeneration; then hepatic insufficiency and ascites occur. Remissions and exacerbations are caused by acute respiratory infections, bringing about a flare-up of thrombophlebitis.

The splenectomies reported are striking examples of this syndrome of development. In all, the respiratory or streptococcic etiology was the most probable. In one of the unoperated cases (Mrs. J. E. K.) there has been a marked improvement on one transfusion and removal of the focus of infection in the teeth. All have exacerbations of their anemia, with thrombo-phlebitis of the spleen following respiratory infection.

No case of splenic anemia should be splenectomized until careful and sufficient observations have been made. It is my belief that splenic anemia can be arrested in its early stages by removal of foci of infection, such as infected teeth and tonsils, which are the portals of entry of the streptococcus. The resistance of the individual at the same time should be strengthened by transfusions.

Splenic anemia in a well-advanced state should be splenectomized as soon as possible after careful preparation by transfusion and rest. If splenectomy is resorted to before an advanced degree of cirrhosis has taken place, complete and permanent cures are obtained. Great care should be observed not to operate in a state of acute thrombo-phlebitis with temperature.

THE RELATIONSHIP OF THE CLINICAL PATHOLOGIST TO SURGICAL PRACTICE *

By VERNE C. HUNT, M. D., Rochester, Minn.
(From the Division of Surgery, Mayo Clinic)

The investigation of the end results of disease by Hunter and the physicians of his time gave impetus to the scientific investigation of disease. With the advance in the art of surgery there has been a parallel advance in the science of pathology, although in the early days of development the two were but remotely related. The extension of vision by the lens has cemented their union until the clinical pathologist has become indispensable to the progress of surgery. The necropsy pathologist will continue to correlate clinical, operative, and anatomic findings, seeking the truth, so that surgical deaths shall not have been in vain.

BY THE sense of sight and through the institution of methods of extending vision, it has become possible to explore still further the mysteries of disease, its cause and manifestations, and to base therapeutic measures on scientific principles.

The science of pathology and the art of surgery possessed little in common until the latter part of the nineteenth century. John Hunter definitely established the science of gross pathology, securing his specimens at necropsy, and made possible the teaching of pathology, not only from clinical subjects, but from actual material removed from the cadaver. Hunter's investigations revealed the ultimate result of disease and afforded opportunity for the study of effects of disease on the various organs of the body, in the gross and by the unaided eye. While the principles of magnification of vision by the microscope were evolved in the seventeenth century, before Hunter's time, yet magnification had not attained a power of more than 270 diameters and aided little in the examination of tissue. However, even so, the latter part of the seventeenth century disclosed the usefulness of the microscope in the cellular description of green plants, the malpighian corpuscles of the kidney, red blood cells, spermatozoa, and so forth. But not until the middle of the nineteenth century was knowledge of morbid anatomy based on the knowledge that the cell was the living unit. The description of the cell nucleus, the nucleolus, and protoplasm led to the cell theory of Schieden and Schwann and to Virchow's "cellular pathology," which was but the application of the cell theory of the botanist to human structures in disease.

The art of surgery, which is older than the science of pathology, owes its early advancement to the knowledge of gross anatomy and pathology, and to the later extension of vision by means of the microscope and various instruments for visual examination of the eye, larynx, esophagus, urinary tract and rectum, and by means of the roentgen ray.

Progress of surgery was retarded in the early days by the suffering occasioned by operative measures, and operations were resorted to only in dire necessity. However, with the discovery of anesthetics, surgery received a new impetus, and the access to the abdomen, chest, and head thus afforded, revealed diseased tissue within these cavities in life that hitherto had been seen only at post mortem. While

* Read by invitation at the meeting of the California Medical Association, Yosemite, California, May 19, 1925.

necropsy examination continues to add to our knowledge of pathology the study of disease in living tissue, made possible by surgery, enables us to obtain more knowledge of the progress of disease, and to institute more efficacious treatment.

Surgery has made possible the study of disease in living tissue, and such study has guided, to a considerable extent, the development of surgery. One is so much dependent on the other that the surgeon can no longer render the patient the greatest benefit without the closest co-operation with the clinical pathologist. The surgeon of today has had abundant opportunity to study gross and microscopic pathology, and the greater his knowledge of pathology, the more reliable is his judgment. However, situated as the surgeon is, he must usually base his judgment on only his knowledge of gross pathology. The inadequacy of familiarity with gross pathology alone is forcefully illustrated by MacCarty's statement that, of 47,434 surgical specimens removed at the Mayo Clinic, 18.2 per cent required microscopic diagnosis, and, further, that 5.7 per cent of all surgical cases which afford surgical specimens have tissue removed for diagnosis during operation, and that microscopic examination of 2.65 per cent of all such specimens does not corroborate the clinical or pre-operative diagnosis. Of these cases, 60 per cent require quite different surgical procedures as a result of the microscopic diagnosis. In spite of considerable knowledge of microscopic pathology, the surgeon, because of his immediate duties, does not have the opportunity to apply that knowledge at the moment, and must depend for the desired information on the clinical pathologist, who should be prepared to supply it without delay. Such pathologists are not numerous, for too often the pathologist is one whose training has been in the study of fixed tissues, to the exclusion of tissues freshly removed from the body.

Progression from the diagnosis of fixed tissues to proficiency in the microscopic diagnosis of fresh tissues demands study of fresh tissue cells. Wilson and others have described rapid methods of preparing fresh tissues for microscopic examination, requiring only a few moments. Inasmuch as the exact determination of the nature of many lesions requires microscopic examination, and since the surgical procedure is so often dependent on the microscopic diagnosis, immediate examination of fresh tissue is indispensable, not only to the surgeon, but to the best interests of the patient. This is particularly true in the diagnosis of malignant lesions. Evidence is not lacking that dissemination of neoplastic cells occurs when a malignant lesion is incised, and microscopic examination of the fixed tissue delays the operation for several days. However, MacCarty and Sistrunk have shown that there is no risk of dissemination in waiting a few moments for microscopic diagnosis in order that the surgical procedure may be governed by the diagnosis of the fresh specimen.

Many methods are available for making clinical diagnoses, yet Cabot has reported an error of approximately 50 per cent in clinical diagnosis. The frequent necessity of removing glands for diagnosis, excising breast tumors for diagnosis, performing diagnostic curetments, and so forth, illustrates the

difficulties of clinical diagnosis. Diagnosis of many pathologic conditions can be made before operation; others can be diagnosed during surgical exploration before tissues are removed, and some can be diagnosed grossly after tissues are dissected and removed; but, as MacCarty has reported, there is a certain percentage which cannot be diagnosed positively without microscopic examination.

In order that the pathologist may become proficient in the diagnosis of fresh tissue, he must have access to all fresh tissue so that he may study the normal and the pathologic, and the intermediate stages between the two. The study of gradations is particularly necessary in the diagnosis of suspected malignant lesions, for they are not of mushroom growth—benign one day and malignant the next. MacCarty has shown that parenchymal germinative cells of some organs undergo certain morphologic changes, and has described the epithelial hyperplasia as primary, secondary, and tertiary, defining these changes, respectively, as benign, doubtful, and malignant epithelial growths. In giving his opinion after microscopic examination, the pathologist requires the surgeon to have sufficient knowledge of gross pathology to be able to excise a representative specimen for examination. Malignancy may be actually present, and the microscopic examination by the pathologist fail to reveal it, unless a representative specimen of the diseased tissue is presented.

The educational campaigns conducted by the American Society for the Control of Cancer can accomplish their purpose only through the institution of methods of diagnosis which will lead to the early recognition of the absence or presence of malignant lesions. That accurate clinical diagnosis is not always possible, is admirably pointed out by MacCarty, who utilizes tumors of the breast for this purpose. He shows that in 20.6 per cent of the cases the clinical diagnosis is not indicative of the true pathologic condition, an uncertainty illustrated by the terms "nodule," "tumor," "mass," "growth," and so forth. Furthermore, he states that 16.7 per cent of all clinical diagnoses of tumors of the breast are incorrect, so far as malignancy and benignancy are concerned, and that 5.5 per cent of all clinical diagnoses of malignant conditions of the breast are incorrect. With educational propaganda these errors of diagnosis are increasing, and they are legitimate errors, for in but a small percentage of instances is it possible to make a correct clinical diagnosis of the exact pathologic process in the breast early in its development, on account of the absence of clinical manifestations by which it may be recognized as benign or malignant. Only by early excision of tumors of the breast is early diagnosis possible. After excising the tumor the surgeon or pathologist may be able to make a diagnosis on gross appearance, but MacCarty has shown that 18 per cent of all carcinomas of the breast have not been positively diagnosed by the clinician or surgeon and have required microscopic diagnosis. It is unquestionable that even careful clinicians and excellent surgeons make such mistakes. To correct such clinical errors and supplement the diagnostic ability of clinician and surgeon demands the services of an expert clinical pathologist for the examination of the fresh tissue. When the diagnosis is questionable or the significance of the

clinical manifestations or gross appearance is in doubt, the scope of the surgical procedure depends on the pathologist's verdict.

No longer may the surgeon who has not readily accepted the advantages of fresh tissue diagnosis fortify his objections with the statement that when he has been in doubt from clinical manifestations and gross examination of tissue the pathologist has also been in doubt. In studying fresh tissue, the pathologist has been enabled to study living cells and has observed those cellular changes which occur during the intermediate stages of development of a lesion from benignancy to malignancy; and he who is adequately trained is not in doubt in the recognition of such changes. Considerable difference of opinion may exist among pathologists expert in the microscopic examination of fixed tissues, but it is unquestionable that cellular degeneration, by virtue of the length of time since the death of the tissue, even though fixed, may be partly responsible for the disagreement. It would seem that pathologic processes and nomenclature will be standardized only through the study of fresh tissue.

It has been a frequent clinical observation, in following the post-operative results of the treatment of malignancy that some patients live much longer than others, even though the lesions were of approximately the same degree of development and were treated by the same methods of excision. MacCarty, Powell, and others have shown that such microscopic manifestations as lymphocytic infiltration, fibrosis, hyalinization, and cellular differentiation exert a marked influence on post-operative life, and that the average post-operative life is longer when these factors are present singly or in combination. These observations suggest that such activities play a significant part in the natural defense mechanism against cancer after it has once developed.

Broders has indicated that cellular activity exerts a marked influence on the progress, clinical manifestations, and ultimate results of treatment of cancer. He has utilized cellular differentiation as a means of grading the degree of malignancy in epithelioma, classifying malignancy under four grades, each dependent on the amount of differentiation of the epithelial cell. The most highly malignant epithelioma shows little or no tendency toward cellular differentiation. If about three-fourths of the epithelial cells are differentiated and one-fourth undifferentiated, the malignancy is graded 1; if the differentiated and undifferentiated cells are about equal, it is graded 2; if the undifferentiated cells form about three-fourths and the differentiated about one-fourth, it is graded 3, and if there is little or no tendency toward cell differentiation, it is graded 4. The number of mitotic figures and the number of cells with single, large, deeply staining nuclei, play an important part in the grading. Clinical application of this method of grading has shown that those epitheliomas in grade 1 are indolent in growth, tend to remain localized lesions without an early tendency to metastasize, and possess little tendency to recur after removal, whereas those in grade 4 are rapid in growth, extend locally, metastasize at an early age, and tend to recur after most radical removal.

In the correlation of the microscopic grading and

post-operative results in several thousand patients treated, Broders has shown that excision of epitheliomas showing malignancy of grades 1 and 2 is accompanied by a high percentage of cures, while those of grades 3 and 4 frequently recur within five years following radical excision. Broders' contribution marks a most important advance in correlating the science of pathology with the art of surgery. Determination of the degree of malignancy of a given tumor by examination of the fresh tissue, obtained by non-operative methods before operation, or obtained during operation, helps in determining the justifiable magnitude of operation and a relative prognosis. The application of this or other means of determining the degree of malignancy makes possible the standardization of methods of treating malignant lesions and of judging the relative merit of various forms of treatment for the different types of malignant disease.

NECROPSY

Supplementing diagnostic ability, presenting methods of measuring degrees of malignancy, and supplying a means of relative prognosis, the clinical pathologist has come to occupy a permanent position in relation to the most efficient practice of surgery. However, in order that errors in surgical judgment may be minimized, causes of failure of technical procedures recognized, and causes of death ascertained, necropsy examinations are essential after all surgical deaths. Too often such examination is looked on merely as a means of determining the cause of death. In view of the gross inaccuracy of vital statistics, this is just cause for necropsy, but in order that the surgeon may improve his diagnostic and surgical judgment he must seek the exposition of his errors of omission or commission, which can be obtained only in the carefully conducted necropsy. Inasmuch as but a small proportion of post-operative fatalities are coroners' cases, it is possible to obtain necropsy only through appeal. The frequency with which consent for necropsy examination is obtained is usually directly dependent on the sincerity of the desire for such examination. The surgeon who has exercised his best diagnostic and surgical judgment and operated in perfect sincerity and with confidence of a favorable result, possesses sufficient temerity not only passively to allow necropsy but sincerely to desire and actively seek it. His efforts are usually fruitful. Wilson has shown that as the value of necropsies to the progress of surgery became apparent, post-mortem examinations at the Mayo Clinic increased from 22 per cent in 1904 to 95 per cent in 1915, an average of about 85 per cent having been maintained since then.

Necropsy not only discloses causes of death and facts by which surgical judgment may be enhanced, but often shows that certain important features of disease, perhaps not recognized by clinical examination or surgical exploration, have been contributory causes of death. Furthermore, it often discloses a remote distribution of the primary disease which may be impossible to determine clinically or by exploration. The surgeon who welcomes necropsy will profit by what he sees, his perspective of disease will be broadened, his diagnostic and surgical judgment

ripened, and an opportunity to measure his surgical limitations afforded.

The necropsy pathologist may contribute to a better selection of patients for operation, a reduction in mortality rate, and a reduction in post-operative complications, if he has the opportunity to present the complete picture of all tangible morbid processes at formal pathologic conferences attended by all physicians associated in the care of the patient. The presentation of the case history, clinical diagnosis, operative procedure, post-operative course, and necropsy findings leads to an otherwise unobtainable perspective of disease, and affords opportunity for complete correlation of clinical, operative, and post-mortem findings. Criticism by the necropsy pathologist of the judgment exercised in technical procedures and subsequent management in their relation to anatomic findings at necropsy, not directed as a personal attack but in a friendly, impersonal, not undebatable manner, is received by the surgeon and clinician in the same spirit, and may contribute to the enhancement of service and to the benefit of mankind.

SUMMARY

The investigation of the end-results of disease by Hunter and the physicians of his time gave impetus to the scientific investigation of disease. With the advance in the art of surgery there has been a parallel advance in the science of pathology, although in the early years of development the two were but remotely related. The extension of vision by the lens has cemented their union until the clinical pathologist has become indispensable to the progress of surgery. The necropsy pathologist will continue to correlate clinical, operative, and anatomic findings, seeking the truth, so that surgical deaths shall not have been in vain.

MANAGEMENT AND TREATMENT OF BURNS

By H. J. RING, M. D., *Ferndale*

I HAVE tried all the standard treatments and about every new method for the treatment of burns presented to the profession during the last forty years, as opportunity offered, with the result that I have finally adopted a certain way or method of handling all burns of every degree of severity, and I now obtain uniformly good results in every patient where a cure is possible. The principles to be observed in all burns of every degree are as follows:

1. To overcome and relieve the pain as quickly as possible.
2. The immediate application of a permanent dressing.
3. A permanent dressing that will preserve and conserve as much injured tissue and skin as possible, and overcome the shock from the injury.
4. Dressings that are removable and that may be renewed without pain or injury.
5. Dressings that will prevent sloughing, pus formation, and bad odors.
6. Early restoration of function without defects.
7. Due consideration of cosmetic effects.

All these principles are covered by just two varie-

ties of dressings, both simple and effective and ever ready at hand, as needed at either home or hospital. The first and immediate dressing to be used is a paste of bicarbonate of soda (either chemically pure or the commercial kitchen brands) with cooled, boiled water, applied directly to cover the entire burned area and made to stay with gauze or bandages saturated with the same paste. More paste is then applied over the bandages to make a complete thick, moist layer over the entire injured surface. The parts are then covered with a light towel wet with a saturated solution of the same soda, and finally the whole is enclosed in oiled muslin or oiled silk, with just sufficient bandages to retain all the dressing in place. The oiled silk or muslin covering should be opened at regular intervals and the dressings again saturated with cold saturated solution of the bicarbonate of soda, always properly prepared. The dressings must be kept moist to prevent the soda from drying and caking. The paste dressings are renewed once a day, employing a saturated solution to remove any cake or crusted soda, and using care not to wash or disturb the injured skin blisters or other tissue. The second and subsequent dressings are made, applied and kept moist, as described for the first one. These dressings should be continued, with daily renewals, for at least four or five days in every case, and in deeper burns until beginning separation of the destroyed tissue. The first dressing quickly relieves the pain and overcomes shock. Its continuous application acts to conserve and restore injured skin and other tissue, prevents the acid fermentative processes present with other dressings in the separation of destroyed tissue, thereby also preventing fever, bad odors, pus formation, and infection. Blisters must never be opened because, if left alone, skin formation will take place under every dried blister and thus diminish the danger of scarring. Should blisters break, continue the soda dressings until the old skin flattens to the level of normal skin and until beginning separation of destroyed tissue in the deeper burns when it may be discontinued and the second permanent dressing applied, which is a simple ointment, as follows:

R Bismuth Subnit $\frac{5}{16}$; Ung. Zinci Oxid. $\frac{5}{8}$; ft. Ung. (This oxide must always be prepared from benzoinated lard, never from vaseline.)

Sig: Apply direct to the skin, open sores, or denuded surfaces, or on gauze, to completely cover all parts affected. It may be renewed once or twice daily, without removing what may be adhering to skin or other parts, but adding fresh or new to keep all involved parts constantly covered. In case of painful, irritable deep sores at the time of separation of dead tissue, the addition of from one to two grains of sulphate of morphia to every two ounces of ointment, according to age of patient, will give entire relief and should be discontinued after a few days' use. This dressing prevents pus formation, serous oozings, and bad odors. It is clean and very comfortable to the patient, allows free movements of parts, and produces the best possible restoration of function and cosmetic effects, without adhesions or contractions, and must be continued until good, healthy, strong skin again covers the area affected. Oiled silk or muslin should be used outside of the other dressings until all sores are entirely healed. In

case of too prolific or redundant granulations in deep burns over large areas, apply a little of a 20 per cent solution of argyrol when renewing dressings, once a day or every other day as may seem necessary, and with this dressing you will rarely need to resort to skin grafting, even on extensive raw open surfaces.

MORTALITY RATES OF CARCINOMA OF THE UTERUS IN CALIFORNIA

By ALFRED BAKER SPALDING, M. D., *San Francisco*

In California, with an annual total number of deaths of from 52,000 to 54,000, it has been found that the total cancer mortality averages about 8½ per cent, which means an annual cancer death rate in the neighborhood of 4500.

It does not seem probable that cancer starts from a single cell, but rather that simultaneously many cells in a particular upset environment develop about the same time malignant characteristics.

DISCUSSION by Frank W. Lynch, *San Francisco.*

OUR ideas on the incidence and the mortality rates for cancer are based at present upon statistics gathered by various boards of health, by some hospitals, and by life insurance companies. The gathering of these statistics is an exceedingly complicated matter and calls for much expert understanding. Not until recently have any satisfactory figures been published. These corrected statistics have come chiefly from the larger insurance companies. At first glance it appears that malignancy is becoming alarmingly more frequent and some conscientious statisticians believe that cancer is increasing at the rate of 2 per cent a year. This impression is due in part to the fact that the older statistics report that only about forty individuals per hundred thousand died annually from the disease, while now many cities report over 100 annual cancer deaths per 100,000 population. In the United States the registration area for vital statistics is quite extensive and is most conscientiously supervised. Still, it suffers from unavoidable errors incident to the various factors which cause a physician to render, at times, an incorrect certificate as to the cause of death. Even with our own limited experience, we know of patients who have died of carcinoma of the uterus whose certificates of death state, with truth, that they died of heart disease or of an accident.

In California, with an annual total number of deaths of from 52,000 to 54,000, it has been found that the total cancer mortality averages about 8½ per cent, which means an annual cancer death rate in the neighborhood of 4500. Of these cancer deaths, the genital organs furnish 14½ per cent.

San Francisco presents an unique situation, in that it ranks highest in cancer deaths by a very wide margin, rating 132 annual cancer deaths per 100,000 population, while the combined average of nine other cities of the United States is only 104 per 100,000. Los Angeles ranks seventh, with a rate of 102 per 100,000 population. Due to this fact, San Francisco has been selected as a city that would prove interesting for cancer research and through the Hoffman Survey, the San Francisco Board of Health is now getting ready to carry out this work along very elaborate and comprehensive lines.

Doctor Frederick L. Hoffman has requested that the local medical profession assist him in a San Francisco cancer survey, by replying to a questionnaire regarding every cancer patient under treatment during the year 1924. These questionnaires are somewhat extensive, and will require considerable careful work on the part of the attending physician, but the result to be obtained is so important that we all should be more than willing to assist in this work.

To me, it does not seem probable that cancer starts from a single cell but rather that simultaneously many cells in a particularly upset environment develop about the same malignant characteristics. Just how long it takes for these few malignant cells to develop a noticeable cancer tumor that is histologically characteristic and produces symptoms noticed by the patient is unfortunately an unknown factor. Possibly what we speak of at the present time as a pre-cancerous stage is this early stage of cancer development. The duration of the disease from the onset of noticeable symptoms, such as hemorrhage, to the death of the patient is better known. While the course of the disease may, in one case, be very slow and in other cases very rapid, the usual time noted is somewhere in the neighborhood of two years. That has been our experience at Stanford, with a few cases observed where no treatment for the cancer had been carried out.

The patient is certainly fortunate who has a microscopical diagnosis of early carcinoma of the uterus, but the patient who comes for treatment a year after symptoms develop or who has been subjected to improper and incomplete surgery, with all the visible evidence of ulcer formation, or, still worse, cancer recurrence, is, in our experience, in a practically hopeless condition, so far as cure is concerned. So far-reaching is this that it seems justifiable and ethical to inform women over 30 years of age of the importance for routine pelvic examination at reasonable intervals, even though no symptoms exist.

Pinch very justly deprecates the statement at times appearing in the lay press that radium and other forms of radiation therapy are a failure and suggests that the term "cure" for advanced cancer cases be changed to "arrest of disease." Radiation therapy is an invaluable addition to our armamentarium for the care of the cancer patient. It is undoubtedly curative when used early enough, and frequently patients with advanced cancer have lived in comparative comfort after such treatment when all other resources of medicine and surgery had been exhausted. However, the only cures I have to report have been obtained with patients operated upon early by radical complete hysterectomy, in some cases aided by radium or x-ray either before or after operation. In the early stage of the disease, with this form of treatment I have 31.2 per cent of cures without recurrence in from three to seven years, with a series of thirty-two patients. The immediate operation death following hysterectomy was six, or a mortality of 19 per cent. This is somewhat higher than that usually reported, and is due in part to the inexperience of early clinic years. The last immediate mortality following hysterectomy was on March 1, 1918. During the past six years we have

had at Lane Hospital no immediate fatalities which can probably be accounted for by better staff organization and improved technique. With no other form of treatment have we succeeded in curing a patient for three or more years that ultimately did not die or have a recurrence, although we have two of forty-two radium-treated patients alive and free from recurrence since 1921, as against two of seven patients treated by operation alive and free from recurrence for the same length of time.

My present preference in choosing a method for treating the early case of carcinoma of the uterus is to treat the patient with radium and x-ray before operation; in about five weeks to do a radical hys-

terectomy with removal of parametrium and to avoid post-operative radiation, except for the treatment of recurrence. All suspected cancer patients are subjected to a diagnostic curetage and excision of cervix specimen, inserting 100 mg. of radium while awaiting a frozen section diagnosis. If found malignant, the radium is left in the uterus from twenty to thirty hours. The radiation department advise in each case as to the need of deep x-ray therapy. When deep x-ray therapy is used, we usually divide the treatment into two stages, with one-day interval. In an average case, the factors are approximately as follows: With a target skin distance of 50 cm., 300 to 450 milliamperes minutes

Thirty-two Hysterectomies gave 3 to 7 years cures in 31.2 per cent. Thirteen Hysterectomies had radium as auxiliary. Six were carcinoma of cervix. One was carcinoma of body.

are given through a round port 25 cm. in diameter centered over the front of the pelvis, a $\frac{3}{4}$ mm. copper filter and 200,000 volts being used. On the following day a similar port is radiated over the back.

The accompanying charts state graphically my private and clinical experience with the 117 cases of cancer of the uterus treated from August, 1912, to April, 1924. With the patients treated before 1921, 71 per cent either died or had recurrence. Fifteen per cent were without recurrence from three to seven years, while 14 per cent were without recurrence so long as traced, being lost track of, however, before the three-year period was reached. Fifty per cent were operated upon, of whom 31.2 per cent were cured and 19 per cent died as a result of operation. Since 1921, radium and deep x-ray has been used more extensively, and only 15 per cent of the patients have been operated upon. The time is too short to judge fairly the comparative value of radiation versus operation, and the problem is more complicated because since using radium and deep x-ray therapy, although more patients are being received for treatment, a much larger percentage of the patients show advanced cancer growth. Of twenty-five patients dead after radiation treatment, the life duration was less than with twenty patients dead after operation. However, of the twenty-five patients dead after radiation, one died of an accident, one of a heart lesion, five had had incomplete operations by outside doctors before radiation treatment, and two died following hysterectomy by their family physicians after radium.

The prognosis for early cancer of the uterus is so good and a fatal outcome for advanced carcinoma of the uterus, regardless of treatment, is so sure that the greatest hope for reducing the apparently increasing cancer death rate seems to lie in more frequent routine examinations by the family physician, the prevention and eradication where possible of all local and general irritations, the earliest possible pathological diagnosis in suspicious cases and in proven cases, the pre-operative use of radium and deep x-ray followed in a few weeks by complete radical removal of the uterus and parametrium.

Stanford University Hospital.

DISCUSSION

FRANK W. LYNCH, M. D. (University of California Hospital, San Francisco)—I believe that a statement of some of my findings would be of interest in connection with Doctor Spalding's paper, because, first, my observations agree absolutely with his and secondly, because the tables from our respective clinics undoubtedly represent a very considerable proportion of the uterine cancers in San Francisco during the period covered.

Since July, 1915, I have treated 218 patients for carcinoma of the uterus, but, for present purposes, will exclude all the cases that were neither radiated nor operated. We will begin our series in March, 1916, when I did the first radical operation in the present group. Between that time and October, 1923, I have treated 168 uterine cancers by operation or radium or in combination. The series should be closed January, 1920, to permit a study of cures, since I cannot discuss any case that has stood less than five years from the standpoint of cure. Our series, however, is so small that it probably will never be large enough to permit the discussion of the broad question of cures.

The chief trouble with small series is that a few unusual cases give false values. Ours may well suffer

from such a reason. Yet few may ever hope to present a series as large and well controlled as Wertheim's unsurpassed group of 1500. Our material presents 168 cases divided as follows:

TABLE I

148 carcinoma uterine cervix, 114 no previous operation for cancer, 34 operated for cancer by others, sent in for post-operative radiation.
20 carcinoma uterine fundus.

CARCINOMA OF UTERINE CERVIX

TABLE II

Primarily operable, 30 (26 per cent of 114).
Refused operation, 2.
Operation contra-indicated, 5.
Operated by radical method, the majority with pre-operative or post-operative radiation, 23.
(Four deaths—17 $\frac{1}{3}$ per cent.)
Radiated only, 7.

TABLE III

Operated between March, 1916, and Dec. 31, 1920, 19.
Died from operation, 4.
Died from cancer, 4, at 9 months, 1 year, 1 year, 3 $\frac{1}{2}$ years.
Died from intercurrent disease, apparently free from cancer (no autopsy), 2. One stroke at year, 1 pneumonia at 5 years.
Lost, 4, but well at 2, 2 $\frac{1}{2}$, 3 and 3 years after operation.
Living and well, 5, at 3, 4, 5, 5 $\frac{1}{2}$ and 7 years after operation.
Four cases of the nineteen were known to have been clinically well at least five years (21 per cent). Nine of the nineteen were well for a minimum of three years: one dying later from cancer; one at five years from pneumonia; two have been lost; and two are still short of a five-year period of observation.

TABLE IV

Operable cases radiated only, 7.
Deaths from treatment, 0.
Died from heart attack, symptom free from cancer, 1, at one year.
Died from cancer, 3, at 3, 3, and 3 $\frac{1}{2}$ years after treatment.
Clinically well, 3, at 3, 4 $\frac{3}{4}$ and 5 years after treatment.

TABLE V

Inoperable cervical carcinoma, made operable by radium, 4 living at 1 year with recurrence; 22 months, with recurrence; 2 years and 5 $\frac{1}{2}$ years.
The first two were operated when the growth appeared to be recurring, since it did not again respond to radium. The last two were operated while the growth appeared to have been controlled by radium.

TABLE VI

Inoperable cervical carcinoma radiated only, 80.
Lost, 2.
Dead, 64; 44 in first year, 9 in second year, 4 in third year, 7 in fourth year.
Living, 14; 7 less than 2 years, 3 in third year; 3 in fourth year; 1 in fifth year.

TABLE VII

Cancer of cervix operated elsewhere, radiated by me, 34.
Living, 5, at 1 year, 2 $\frac{1}{2}$ years, 3 years, 3 $\frac{1}{2}$ years, 5 years.
Dead, 29, 4 only lived more than 2 and less than 3 $\frac{1}{2}$ years.

CARCINOMA OF UTERINE FUNDUS

TABLE VIII

Carcinoma of uterine fundus, 20.
Operated radically, 9.
Operative death, 1.
Dead from disease, 1, in 6 years.
Lost track of 2, both well at 1 year.
Living with recurrence, 2, at 1 and 2 years.
Living and well, 2, at 3 and 7 years.

REPORT OF RESULTS OF INSULIN TREATMENT IN A CASE OF PREGNANCY COMPLICATED BY DIABETES MELLITUS AND FUNNEL PELVIS.

By LINDSAY PETERS, M. D., *Alameda, California*

ALTHOUGH diabetes mellitus is a widespread affliction, its occurrence as a complication of pregnancy is rare, because diabetic women are generally infertile (Lublin). In the statistics of Van Noorden, pregnancy occurred in only 5 per cent of 427 diabetic women of child-bearing age.

When, however, true diabetes mellitus does occur during pregnancy, either as a new development or as a condition antedating the pregnancy, its effects are very often disastrous either for the mother or the child, or both. Although in a certain proportion of cases the child is carried to or near term without serious results, in the majority of cases the disease is aggravated by pregnancy, and commonly results in coma and death. In 1908, Offergeld collected sixty-three cases from the literature where diabetes complicated pregnancy. Of these patients, 30 per cent died in coma, and 66 per cent of the children died. Thus, before the era of insulin, death of the mother and the fetus in utero were quite common, and when the child was born alive it was apt to be premature and puny and sometimes hydrocephalic or affected with congenital diabetes. Hydramnios is a frequent complication, which results in death or premature birth of the infant. De Lee, while pointing out that "insulin will enable us to tide diabetics along in pregnancy until the child is viable, it will help the patient to withstand the effects of labor (used prophylactically), and it is a positive aid in diabetic coma," cautions, nevertheless, that "one must not expect too much from it, because certain cases of diabetes are aggravated by the pregnancy and will not clear up until the pregnancy is removed." He advises that, on account of the need of experience, all cases of pregnancy diabetes should be put on record, especially those treated with insulin.

I have been able to find in the literature only three reported cases in which insulin was used to combat diabetes complicating pregnancy: Wiener reports a case, with hydramnios, in which the child was still-born, but the mother's life was saved by the use of insulin. Reveno reports a case of diabetic coma in pregnancy in which, with insulin treatment, the mother recovered, but the premature infant died after sixteen hours.

Ambard et al. observed "a woman, aged 35, with grave diabetes, who gave birth (eighth month) to an infant with diabetes (12 gm. sugar per liter of urine). The mother died in a few hours, the child after twenty-three hours. Necropsy showed lesions in the maternal and in the fetal pancreas. Evidently, the diabetes developed in the woman because the pancreas deficiency was not compensated by the affected fetal pancreas. The fatal outcome, after hyperglycemia had disappeared under insulin treatment, is ascribed by Ambard and his co-workers to lesions of the liver and kidneys, caused by transient acidosis."—Abstract in *Journal A. M. A.*, June 6, 1925, vol. 84, par. 1786.

The case here reported illustrates the beneficent effect of insulin in a diabetic patient who had previously lost a child at six months in a pregnancy complicated by hydramnios, but, incidentally, it is

also of interest as a striking example of marked contraction of the outlet of the bony pelvis in which a combination of favorable circumstances resulted in spontaneous delivery of a living, healthy child. Notwithstanding these two serious complications, either one of which gave grounds for anticipation of grave trouble, the pregnancy, labor, and lactation were exceptionally free from difficulty.

Mrs. M., aged 22 years, came to me February 24, 1924, in the fifth month of pregnancy. She had scarlet fever in early childhood, typhoid fever when about 12 years old, and during later girlhood her mother, thinking she had "drinking diabetes," had her urine examined, and this was reported negative.

There was nothing else of interest in her past history, except that she married in April, 1921, and in July, 1923, when 6½ months advanced in pregnancy, she gave birth to a dead child, which caused a considerable laceration. The stillbirth was said to have been due to "excess of fluid" (hydramnios).

The only things noteworthy in connection with the present pregnancy are that the last menstruation occurred October 10, 1923, and during the past three or four months there had been leucorrhoea, accompanied by soreness and itching of the vulva.

The outstanding findings on physical examination were: Fundus uteri at umbilicus; marked vulvitis, with profuse purulent discharge; large amount of sugar in the urine; pronounced funnel pelvis, with measurements as follows: Interspinous, 21.25 cm.; intercrystal, 27.5 cm.; bitrochanteric, 31 cm.; Baudelouque's diameter, 19 cm.; bisischial, 6.5 cm.; posterior sagittal, 8.5 cm. Diagonal conjugate not measured because of inability to reach the sacral promontory.

According to Williams, a bisischial diameter of 6.5 cm., with a posterior sagittal diameter not exceeding 8.5 cm., renders spontaneous delivery at term highly improbable.

By restricting the carbohydrates in the diet to a minimum, the sugar in the urine was much reduced in quantity and this, together with douches and local use of zinc oxide ointment, promptly eliminated the vulvitis, with its attendant itching. However, it was found impossible to maintain the patient's strength on the diet which was necessary to keep the sugar output small, so that on March 22, 1924, the use of insulin was begun. It was found that for a maintenance diet, 10 units three times a day, half an hour before meals, was required. This kept the patient in good condition and the urine either sugar-free or with only a trace of sugar. Insulin was continued until June 15, 1924, one month before the date calculated for maturity of the child, when labor began suddenly with severe uterine contractions at frequent intervals, attended with straining of abdominal muscles, like second-stage pains, which resulted, about four hours later, in expulsion of a female child in occipito-posterior position. During the delivery it was interesting to observe how amazingly the narrowness of the pelvic outlet was overcome by the moulding of the soft frontal bones of the premature child into the narrow cleft of the pubic arch, allowing the occiput to rotate forward over the perineum. It is evident that in this case the posterior position of the occiput was a favorable factor, allowing the frontal bones to become wedged into the narrow space between the pubic rami, with subsequent rotation of the occiput over the peri-

neum. In spite of the prematurity and small size of the child (six and one-half pounds), a moderate laceration of the perineum could not be avoided, on account of backward displacement of the head by the narrow pubic arch. Immediately after birth the head was seen to be greatly compressed laterally in its anterior portion, giving it a wedge shape. The soft tissues overlying the frontal region were purple from ecchymosis, due to severe pressure to which it had been subjected by the narrow pubic arch. The shape of the skull rapidly regained its normal contour and color, and the child thrived, being now apparently normal in all respects, although, owing to hypersensitiveness of the mother on the subject, I have not been able to obtain a specimen of the baby's urine for examination.

The mother had a normal convalescence, and has nursed her baby for nine months. After delivery it was found possible to keep the urine almost free from sugar by means of a restricted, low carbohydrate diet, without the use of insulin, but after about two months it became evident that the patient was undernourished and deficient in strength, so while on a visit to Canada, she, of her own accord, resumed the use of insulin, taking 20 units once daily and increasing the amount of carbohydrates in the diet. She rapidly became strong, gained weight, the skin had a good color, and she appeared and felt herself to be in perfect health. However, on February 17, 1925, she consulted me on account of a return of vulvitis, such as she had when she first came to me. She confessed to having substituted ordinary bread for gluten bread in her diet some time previously, but claimed that urine tests made daily showed no sugar present. She was catheterized at the office and the urine was found heavily loaded with sugar.

A laboratory test on March 7, 1925, showed: Glucose, 7.1 per cent; phenylhydrazine test positive for glucose; blood sugar, 374 mgms. per 100 cc. The specimen for blood-sugar test was taken four hours after breakfast, before which 8 units of insulin were taken. The blood sugar should have reached its lowest point at this time.

The laboratory report makes it clear that we were dealing with true diabetes mellitus and not lactosuria, alimentary glycosuria, nor the so-called renal diabetes which are frequently found in the gravid state.

In summary the case shows:

1. That in a patient who had hydramnios and a premature stillbirth in her first pregnancy, by the aid of insulin it was possible to carry her through a subsequent pregnancy to near term and for her to nurse her child without physical detriment.
2. That with high degree of contraction of the pelvic outlet spontaneous delivery of a premature but vigorous child, in occipito-posterior position, occurred.

We are receiving many compliments on the Medical and Surgical "Conversaciones." Several new ones are being started. If you want to take part in them, tell the editor about it.

TREATMENT OF ACNE VULGARIS

By ERNEST K. STRATTON, M. D., San Francisco

(From the Department of Dermatology and Syphilology, Stanford University Medical School)

X-ray is the best therapeutic remedy we have for the permanent cure of acne vulgaris.

The pustules and subcutaneous abscesses should be cleared up surgically and with the aid of vaccines before beginning x-ray therapy.

The amount of x-ray necessary to effect a cure can be greatly reduced if the hyperkeratotic layer of the skin is first removed by peeling.

In order to avoid the serious sequelae which sometimes follow the injudicious use of the x-ray, it is a better policy never to allow the combined fractional dosage to exceed a skin erythema dose, without giving the patient at least a two-week rest period.

FOR convenience and for the purposes of this discussion, acne is presented under three group headings:

Group I includes the juvenile or the most common form of acne vulgaris; Group II, the artificial acnes, caused from both internal and external irritants, such as the ingestion of iodides and bromides and the local applications of or contaminations with the tars, oils, paraffines, etc.; and Group III, acnes of obscure etiology, which do not respond satisfactorily to local treatment, and which occur, as a rule, in individuals over 25 years of age.

Juvenile acne vulgaris, by far the most common type of the disease, comprises some 8 per cent of all skin lesions. It appears first about the age of puberty in certain individuals who have an abnormal skin, as manifested by (a) a dirty yellowish or grayish coloration, (b) by accentuation of the pilo-sebaceous pores, and (c) by a slight thickening of the integument. This kind of a skin not only furnishes the necessary substratum for acne, but associated with it is a marked increase in the sebaceous gland activity. To this whole picture Darier has given the name "kerosis," and he believes these manifestations to be closely related to sexual development, as they are especially noted at two periods of life, namely, at the time of birth, when some infants are covered with a greasy epidermic covering known as vernix caseosa, and then again at puberty, when the genital function is becoming established.

There is formed in the sebaceous follicles, under appropriate conditions, a mixture of sebum and horny cells, cylindrical in shape, whose exposed surfaces become black, not by a deposit of dust as is generally believed, but through the oxidation of the keratin, and thus we have formed the primary lesion of acne vulgaris, commonly known as the blackhead or comedone.

Comedones, in addition to acting as foreign bodies, furnish by the very nature of their composition, an excellent culture media for many bacteria. The one most constantly present is the microbacillus of Sabouraud, which is morphologically identical to the acne bacillus of Unna. Irritants thus activated cause a dilatation of the vessels in the subpapillary zone about the follicles; there is an infiltration of round cells, and the result is the formation of the papule. This process usually goes on to formation of pustules, superficial or deep, depending, as a rule, upon the virulence of the secondary

invading pyogenic organisms. The usual benign character of the suppuration, its freedom from pain and its slow development is most generally due to the non-virulent staphylococcus albus. The different lesions are often associated in the same patient, thus explaining polymorphous acne, consisting of comedones, papules, pustules and, occasionally, subcutaneous abscesses.

The treatment of this type of acne should first of all be directed to the correction of any constitutional disturbance which may play an equally important part, such as habitual constipation, dyspepsia, improper diet. Sugars and starchy foods especially should be reduced because they have a tendency to increase sebaceous secretion.

On the whole, however, the relief of acne depends essentially upon intelligent local treatment. The first step is to get rid of the pustules and subcutaneous abscesses, which is best accomplished by incising them and maintaining drainage with a hygroscopic wet dressing, preferably alkaline. A formula for a satisfactory one is 8 per cent magnesium sulphate or sodium chloride, 8 per cent sodium bicarbonate, and 4 per cent boric acid solution. While many experienced dermatologists doubt the value of vaccine therapy in acne, I believe that it is especially beneficial as an aid in clearing up the pus. The best results are obtained with the use of the stock-mixed staphylococcus vaccines. Results are disappointing, however, in other than the pustular variety, in which I administer routinely this vaccine, as well as the combined acne vaccine.

After the pustules have disappeared there still remain papules, comedones, and a thickened skin to deal with. Therefore, the next indication is to get rid of the thickened skin; this is accomplished by peeling. There are many remedies for the purpose, and they can be incorporated in ointments, pastes, or lotions. Lotions are cleaner, and one consisting of 2 grains of bichloride of mercury, $2\frac{1}{2}$ drams each of salicylic acid and camphor in 3 ounces of alcohol, if applied twice daily after the skin is scrubbed thoroughly with soap and warm water, will cause the removal of the hyperkeratotic condition in from four to seven days.

The skin is then ready for x-ray therapy, and a surprisingly small quantity of it is needed to clear up the papules after the skin is first prepared as indicated. Begin with 10 per cent of an erythema-producing dose and give five weekly treatments, increasing the dosage 5 per cent each week. This is an effective, as well as a safe method of treatment. In the aggregate, such intermittent dosage does not exceed a single skin erythema-producing dose. Should the trouble prove recalcitrant, however, the roentgen treatment can be repeated after an interval of two weeks.

The comedones, which are the only remaining lesions to be dealt with, should be removed mechanically at least once a week by means of a Bronson curette, and followed after one month by .5 to .75 of a skin unit of unfiltered x-ray. This causes an atrophy of the sebaceous glands, and with the diminished output of sebum the comedones will disappear. Lotio alba or boric acid in alcohol is useful locally during the treatment of the papules and comedones.

The scalp should receive attention from the be-

ginning, as it usually presents an oily pityriasis which may be controlled with a 10 per cent sulphur and 5 per cent salicylic acid ointment, together with thorough shampooing. The result is practically permanent, the patient never having more than an occasional isolated lesion thereafter.

Artificial acnes, resulting from the ingestion of large quantities of bromides and iodides, may appear in the usual acne areas. The bromide eruption usually consists of rather large crusted papulo-pustules, which are easily recognized. The iodides, however, cause many small follicular papulo-pustules, sometimes closely resembling a true acne, but the fact that the lesions are all of the same type and not associated with comedones or a seborrhoea indicates inquiry as to possible drug ingestion. Drug eruptions are probably due to the irritation produced during the process of excretion of these chemicals through the sebaceous follicles. The treatment naturally demands the withdrawal of the causative agents. Locally, mild antiseptic lotions are useful, and the intravenous injection of normal salt solution will sometimes hasten their elimination.

The artificial acnes, resulting from various local agents, are produced by the mechanical occlusion of the follicular orifices. Workers in tar, oils, particularly paraffin oil, are prone to develop this type. The lesions may occur anywhere on the body. The treatment consists of thoroughly scrubbing the part with soap and water, the application of a mild antiseptic and soothing paste, and by protecting the skin from future exposures.

Finally, there is a group of acnes in which the cause is difficult to locate. Fortunately, they are not as numerous as are the other types, but after having treated some of them locally, as hereinbefore outlined, for periods of several weeks without obtaining the desired results, and then seeing them clear up immediately on the removal of an infected ovary, appendix, tonsils or teeth, I then realized that, even in their beginnings, they had not presented the classical picture of acne vulgaris. Such atypical acne is seen, as a rule, in women over 25 years of age. Usually the eruption is more or less limited in extent, and either localized on the chin—a very favorite site—or to circumscribed areas on both cheeks. These patients require certain aid by local treatment, but I believe their permanent cure depends on the removal of focal infections, endocrine imbalance or some other chronic condition which may be causing a reflex flushing of the face, follicular congestion and atony of the skin, all of which finally lead to seborrhoea, the formation of comedones, and ultimately to the development of acne lesions.

CONCLUSIONS

1. X-ray is the best therapeutic remedy we have for the permanent cure of acne vulgaris.
2. The pustules and subcutaneous abscesses should be cleared up surgically and with the aid of vaccines before beginning x-ray therapy.
3. The amount of x-ray necessary to effect a cure can be greatly reduced, if the hyperkeratotic layer of the skin is first removed by peeling.
4. In order to avoid the serious sequelae which

sometimes follow the injudicious use of the x-ray, it is a better policy never to allow the combined fractional dosage to exceed a skin erythema dose without giving the patient at least a two-week rest period.

490 Post Street.

SOME PROBLEMS IN THE MANAGEMENT OF TUMORS OF THE URINARY BLADDER

By PAUL A. FERRIER, M. D., Pasadena

Papillomas should be fulgurated.
Malignant papillomas should be given a trial with fulguration and radium implantation through the cystoscope.
Papillomas which do not respond to the above procedure, multiple or extensive papillomas, those around the bladder neck, cases with uncontrollable bleeding or intolerant to cystoscopy should be treated by open operation.
Small cancers, favorably located, should have a cautery excision with meticulous care to avoid implants.
Multiple cancers confined to the bladder, especially if they involve the sphincter, call for total cystectomy.
Radium alone implanted through the cystoscope has had many apparent cures and is worthy of further trial in the hands of those who are prepared to implant needles accurately throughout the growth.
Deep x-ray should cover the regional lymph nodes in every cancer of the bladder.
Manifestly hopeless cases should not be tortured by ineffective measures. Cystostomy, nephrostomy or nothing.
Large cancers, having a reasonable amount of normal bladder and sphincter and one uninvolved meatus, should be removed by diathermy, followed by implantation of radium needles, through every cubic centimeter of tumor base, screened radium topically, supplemented by deep x-ray therapy of the regional lymph nodes. This method should supplant extensive resections and is, I believe, the greatest recent advance in the treatment of extensive cancers of the bladder.
DISCUSSION by Wirt B. Dakin, Los Angeles; Granville MacGowan, Los Angeles; R. L. Rigdon, San Francisco; Frank Hinman, San Francisco.

GREAT advances have been made in the treatment of tumors of the urinary bladder—fulguration, radium, improved operative technique, deep x-ray therapy, diathermy. This discussion is an attempt to evaluate available therapeutic procedures in the light of pathology and accumulated clinical data, so that the best procedure may be adopted for each individual case.

The etiology is unknown. Analine workers show a higher incidence. Maude Hamilton attributes this to arsenic. Extrophic bladders are more liable to cancer, probably from embryologic fault. Chronic irritation from stone or infection does not seem to play a part.

We adopt Geraghty's classification:

Epithelial	Papilloma	Benign
		Malignant
	Adenoma	
	Cysts	
	Carcinoma	Papillary
		Squamous
		Schirrous
		Adeno

Connective Tissue	Sarcoma
	Myxoma
	Fibromyoma
	Fibroma
	Angioma
Muscles	Myoma
Heterotopic	Rhabdomyoma
	Hydatic cysts
	Dermoid cysts
	Chondroma
	Cholesteatoma

Granulomas and syphilomas must be excluded. Also a villous disease in which delicate streamers arise without pedicle directly from the mucosa. It has been associated with tuberculosis, has been cured by curettage, and is evidently inflammatory.

Epithelial tumors comprise nine-tenths of bladder neoplasms. The great majority of these are papillary or schirrous. Adeno-carcinoma and squamous cell carcinoma are rare and malignant. All are familiar with the difficulty in determining the malignancy of papillary tumors by microscopic diagnosis. Structurally the benign papilloma consists of blood vessels in a branching fibrous stroma, covered with several layers of long-processed, oval; regularly arranged cells, surfaced with normal transitional bladder epithelium. Any irregularity in the size, shape, staining qualities of these cells, the presence of multi-nucleated cells, numerous mitoses with nuclei rich in chromatin, are signs of malignancy, even without a break in the basement membrane. From the fact that ten areas from a tumor may be normal and the eleventh show such a picture, the pathologist's difficulty is obvious. So much so that clinical and cystoscopic data are often more reliable.

The following characters indicate malignancy:

- 1. A fusing or clubbing or tendency to ulcerate of the papillary projections.
- 2. Edema, dilated vessels, velvety patches or submucous nodules about the margin.
- 3. A sessile, lobulated, fissured or ulcerated tumor.
- 4. Very large or multiple involvement with necrosis and urinary incrustation.
- 5. Infiltration of the bladder wall, demonstrable by vaginal or rectal palpation or cystogram with air or opaque medium.
- 6. An intractable cystitis in the presence of tumor.
- 7. A poor response to fulguration.
- 8. Metastasis.
- 9. Finally, microscopic diagnosis of passed or excised tissue.

Metastasis is generally late. Extensive involvement may be found at autopsy, as in two of this series, without demonstrable metastasis. On the other hand, Geraghty reports four cases which showed distant metastases before the bladder wall was involved. The sacral glands are usually first involved, but the bones may suffer early, as in cancer of the prostate. Lower reports metastasis to the brain. Tumors of the anterior wall are more likely to recur than those of the base. Extension to the vesicles and prostate is early, but other extension is usually late.

All papillomas sooner or later become malignant. They may exist innocently for twenty-five years or show malignant histology for years, without infil-

trating the bladder wall. They may be removed and recur as benign or malignant and still not infiltrate the bladder wall. Reference must be made to the extraordinary difference in malignancy of tumors which may show identical histology. Indolent tumors may for no known reason acquire great malignancy.

SYMPTOMS

Hematuria is the warning in nearly all cases. Painless terminal hematuria is particularly suggestive. Casper states that in only three of 142 patients seen soon after the initial hematuria was the tumor large. The duration of symptoms in 181 cases coming to the Mayo Clinic averaged twenty-six months. Sixty-two cases reported by Thomas ranged from two weeks to twenty-five years, while symptoms had been present in seventy-five cases of Caulk for an average of ten years. Frequency and pain are generally late symptoms. It is plain, therefore, that one of the greatest problems in the management of tumors of the bladder is to induce the family doctor and the patient to regard every hematuria as an indication for an immediate diagnosis.

TREATMENT

Benign papillomas, and those in which malignant degeneration has not invaded the pedicle or bladder wall should be fulgurated through the cystoscope.

The following case illustrates the type:

B. R. W. Male, aged 50, referred by Doctor Heddens. For three months he has had slight irritability of the bladder with blood at the end of urination. Cystoscopic examination showed a definite pedunculated raspberry tumor 2.5 cm. in diameter, just back of the right meatus. No necrosis; normal mucosa about the base. Fulguration twice with the D'Arsonval current completely eradicated the growth. No recurrence was noted for two years.

If such growths do not respond promptly, fulguration should not be continued, as they are malignant and will be stimulated. Geraghty and others have found that some of these early malignant cases which are not readily amenable to fulguration will rapidly respond to it after the application of radium.

For fulguration some use the uni-polar current, but the majority prefer the bi-polar D'Arsonval current because it penetrates more deeply. Buerger snares the growth and fulgurates the base. Unquestionably, radium should be implanted in the base if malignancy is suspected. Recurrence was noted in 25 per cent of the cases at Beer's Clinic; 27 per cent at the Mayo Clinic; 29 per cent at Johns Hopkins. It comes, as a rule, within a few months and at the original site. Examinations at intervals of a few months should be insisted upon.

So far the treatment of bladder tumors is agreed upon. Beer states the following contra-indications to fulguration in papilloma:

1. Tumor not readily accessible as about the sphincter.
2. Uncontrollable bleeding.
3. Multiple extensive papillomas.
4. Intolerance of cystoscopy.

For such cases the open operation is necessary.

The further therapeutic armamentarium consists of:

1. Partial cautery resection with infinite care to avoid implantation of tumor cells; total resection in selected cases.

2. Radium implantation through the cystoscope or cystotomy.

3. Diathermy through the cystoscope or cystotomy.

4. Deep x-ray.

5. A combination of these.

Resection of the Bladder—Gardner, in 1915, collected eighty-six cases in which only the growth was excised with 76.3 per cent recurrence in three years, while in fifty-eight cases in which the bladder wall with the growth was taken, 43.9 per cent recurred after three years. Scholl reports in 216 operated cases at the Mayo Clinic 48.2 per cent alive on an average of 3.2 years. Lower, in sixty-one resections, found 67.2 per cent dead, half in the first year. Squier, in 1923, reported results with his segmental resection of the bladder; that is, taking that entire segment of the bladder which drains into the same regional lymphatics with the tumor. It is impossible to remove the regional lymphatics of the bladder. Twenty-eight of the sixty cases were alive from two to eight years; not appreciably better results than with the old method.

Squier, Beer, Thompson Walker, and others have developed a method of surgical attack, with especial reference to avoiding implants. The essentials of this method are:

1. With the patient in the Trendelenburg position, through a long extra-peritoneal incision, free the bladder to the trigone, deliver it, and pack about it.

2. To avoid flooding the wound with cancer cells, have the bladder empty.

3. Open at a distance from the tumor, holding the bladder with smooth forceps.

4. Cauterize deeply the tumors and do a wide cautery excision, including the ureter if necessary.

5. Unless the peritoneum has been opened, fill the entire wound with 70 per cent alcohol for five minutes. Two per cent silver nitrate can be used.

6. Transplant the ureter if necessary.

7. Sere the raw surfaces and close with drain.

No statistics are available, but method, we are assured, is producing better results.

Total Cystectomy—In cases of advanced or multiple carcinomas confined to the bladder, especially those invading the sphincter, total cystectomy is the operative procedure of choice. It should be done in two stages. Scheele has collected sixty-two cases of total cystectomy with thirty-two permanent cures. Transplanting the ureter into the bowel requires great technical skill, and infection of the kidney mars many good results. The safer, though disagreeable procedure, is nephrostomy or ureterosotomy, with ureteral catheters draining into bag.

In all surgical operations on the bladder, pre-operative conditioning of the patient, tests of renal function and heart function, and clearing up infection as far as possible, are of the greatest importance, a lesson learned from prostatectomy.

COMBINATION OF SURGERY, DIATHERMY, RADIUM AND X-RAY

Success with the open method, using the D'Arsonval current, 1500 milli-amperes and a spark gap of .5 cm., and a large burning electrode so as not to produce sparks has been reported by MacGowan, Kolischer, and Corbus. If one meatus is involved, ureteral transplantation will be required, or if the kidney be infected, nephrectomy. Thomas and Pfah-

ler have added the implantation of radium needles into the cauterized base, with subsequent x-ray of the regional lymph nodes, reporting in 1922 twenty-six patients so treated in the previous three years with, up to that time, two deaths and one untraced.

The following case illustrates this procedure:

L. H. Male, referred by Doctor Lockwood. He has had spells of blood in the urine for six years. Two years ago he had complete retention from clots, and now has a hemoglobin of 30 per cent. Blood transfusions were necessary before attempting even a cystoscopic examination. This revealed a necrotic, malignant papilloma seven centimeters in diameter at the base, back of the right meatus, with implants on the opposite wall. The bladder was opened, the growths completely burned away with a bi-polar current, fifty milligrams of radium in needles implanted in the primary base for twelve hours, which was supplemented by an equal amount of fully screened radium on the surface later. This was over three years ago. He has been working daily at his trade, and recent cystoscopic examination showed no sign of recurrence.

Radium Alone—Barringer, by endo-vesicle or suprapubic implantation of radium alone, reported, in 1922, eight of ten cases of small carcinoma free from growth from three months to four years, and twenty inoperable cases with the tumor removed from the bladder for a period of one month to four years, during which three recurrences and one death were noted.

Buerger, in 1923, reports favorable results with radium alone through the cystoscope. It is generally agreed that the best results are achieved by the burying of the radium in the growth. Holding the radium against the growth is generally ineffective and more damaging to the normal mucosa.

Barringer's method is to open the bladder, remove the growth by cautery, and bury one millicurie of radium emanation in a capillary glass tube for each cubic centimeter of tumor. The lethal effect barely extends one centimeter, and the danger of missing some cells is great. Braasch and Scholl found, in histologic study of tumors so radiated and removed, that there were nests of living cells incarcerated by areas of fibrosis. This possibility makes it necessary to supplement the buried, unscreened radiation by topical, screened radiation.

If the urine is diverted from the bladder, comparatively huge doses of radium can be given, bringing hope to hopeless cases.

In using radium, these elementary principles of radium therapy must be borne in mind:

1. That cancer cells are more susceptible to the first radiation than to any succeeding radiation. Those men who treat, for example, carcinoma of the cervix uteri will tell you that the full lethal dose should be applied within six weeks and that subsequent fractional doses do more harm to the host than to the tumor.
2. As a corollary to the first, if tumors do not respond promptly to an adequate dose, they are radium resistant and will never respond.
3. Recurrences after radium do not respond well.
4. There is an enormous difference in the radium susceptibility of any given tumor. Radium has a selective effect on germinating cells. A soft cellular tumor will respond more quickly. But, unfortunately, such a quick growth is evidence of poor resistance of the host, and unsuspected extension or metastases are likely to have occurred beyond the visible area. Experience shows that papillary carcinomas are more favorable than schirrous, squamous or adeno-carcinoma of the bladder.

5. Radium rays, exactly like light, decrease as the square of the distance increases. Therefore, a lethal dose at one centimeter is one-fourth of a lethal dose at two centimeters. This is so simple that a child can understand and yet it is constantly disregarded.

6. Determination of the effective dose must take account of the absorption of radium rays. Therapy with unscreened emanation implants, depends largely on the soft beta particles. Now, one millimeter of soft tissue absorbs half of these, ten millimeters nearly all. It is plain, therefore, that before the comparatively few hard gamma rays can greatly affect tissue at two centimeters, the center will be necrosed. The body can only tolerate a limited amount of the toxemia this necrosis entails. Hence the area radiated at one opening of the bladder is limited. *Radium, from which the soft rays have been screened, is effective at a greater distance. That this is true is proven by hundreds of cases in which permanent suspension of the function of the ovaries has been caused by 1500 milligram hours of screened radium in side of the uterus. Practical experience has shown that needles buried accurately 100 milligram hours per cubic centimeter of cancer, supplemented by screened radium, often succeed in complete destruction of the growth. To make sure of outlying areas and metastases a more general radiation is needed.

Deep X-ray Therapy—This is a drag net for the whole pelvis. Considering the fact that it is the only method of affecting the lymph nodes, draining the bladder, it should be used in every case of malignancy. Experience does not show that it can take the place of local treatment, but the results of local treatment have been shown to be better when supplemented by x-ray.

Palliation—In many advanced cancers, especially with metastasis, the greatest comfort and longest life will be obtained by diverting the urine with no local treatment of the bladder. X-ray, or radium, may stop bleeding in inoperable tumors.

This series comprises eighteen cases:

Benign papilloma	2
Malignant papilloma	1
Papillary carcinoma	5
Schirrous carcinoma	6
Adeno-carcinoma	2
Secondary adeno-carcinoma	1
Squamous cell carcinoma	1

It contains some interesting cases.

Mr. C. Aged 91. Referred by Doctor C. D. Lockwood. He had Bottini cautery operation nineteen years ago by Doctor MacGowan for prostatic obstruction. This relieved him for five years when the trouble recurred. Doctor MacGowan then did a perineal prostatectomy. This gave him about ten years of comfort when pain and obstruction at the bladder neck recurred. He was told at this time that the trouble was due to polypi, and these were removed by fulguration. This gave him some relief, but there has not been the previous comfort since. Recent cystoscopic examination showed further polypi, but also a nodular, slightly ulcerated mass 1x2x2 cm. above the sphincter. Except for a mild cystitis the bladder is normal. No signs of the prostate present.

On account of the intolerable frequency and pain at the bladder neck of a suprapubic cystotomy was done. The growth was found as described, very dense and ulcerated. Section by Dr. A. M. Moody showed it to be adeno-carcinoma. Radium needles were implanted, 1200 mgh.

Subsequent examination showed the growth to have disappeared. It is now three years, and at ninety-four he is active and without signs of recurrence.

Mrs. A. M. Aged 65. Had had bleeding from uterus two years prior to a heavy treatment of 8000 milli-

*For caustic action, radium has no advantage over diathermy. It is for that twilight zone of selective activity on cancer cells beyond the living point of normal cells that its action is invaluable.

gram hours of fully screened radium for an adenocarcinoma of the body of the uterus. The growth disappeared, the uterus became normal in size, and the patient was apparently in good condition.

Two years subsequent to this blood appeared in the urine and cystoscopic examination showed a cauliflower ulcerating carcinoma, extending through the floor of the bladder three centimeters across its base. In spite of the hopelessness of the condition the patient wanted radium, and 500 milligram hours of gamma rays were given against the growth. Thorough deep roentgen therapy was applied by Dr. Carl Parker. Now, one year after, the patient appears in perfect health, the urine is negative and cystoscopic examination shows only a silvery soft scar in the floor of the bladder.

W. H. H. Aged 69. Referred by Doctor Macklin.

Terminal hematuria first noted four weeks ago. No frequency and no discomfort whatever. Urine shows a little blood, no pus.

Cystoscopic examination showed in the center of the dome a tumor 2 cm. in diameter, slightly raised, without papillary projection, but with rugae. No ulceration and the border and remainder of the bladder are normal. It did not melt with fulguration, and tissue removed with the rongeur showed the histology of a rectal growth—typical columnar epithelium with goblet cells. It was believed, therefore, to be of allantoic origin.

Operation showed a growth about the size of a hen's egg outside the bladder, extending toward the umbilicus. In it was a cyst 3 cm. in diameter, filled with colloid material. The growth was adherent to the peritoneum, but did not involve it. Intra-peritoneal exploration showed no secondary growths. Sagittal section shows an infiltrating growth originating in the midline just above the bladder and extending through it at the urachal attachment. Microscopic section shows an adenocarcinoma with intestinal type of cells.

The post-operative course was uneventful. Deep x-ray therapy will be given.

Citizens Bank Building.

DISCUSSION

WIRT B. DAKIN, M. D. (756 Broadway, Los Angeles)—The word problem in the author's title of his paper is certainly very appropriate in dealing with nearly all bladder tumors, whether benign or malignant, with the one exception perhaps of small "young" uncomplicated papilloma. Any personal equations or observations on his part are surely well appreciated by those in close touch with this subject.

Too much importance can not be placed on the portion of his paper in which he endeavors to impress upon the family doctor and the public the seriousness of the first blood noticed in the urine. Another item of interest is the importance of having these apparently well treated and cured patients return at stated intervals for observation.

His review of various authors' methods of surgical attack, with especial reference to avoiding implants, is interesting. Any prophylactic measures in this respect should not be omitted. Personally, "it might appear a trifle strenuous to some in advising the filling of the bladder with 70 per cent alcohol for five minutes as well as the suprapubic wound just before opening the bladder. However, if a large suprapubic drainage tube is used following the operation it would appear that sloughs of nearly any size would easily get out of the bladder.

The author should be complimented upon his careful and studious consideration of this most interesting subject. Recent consideration of this subject from a standpoint of tumor classification in regard to their degree of malignancy should help in deciding what method of procedure to follow in treating these tumors.

GRANVILLE MACGOWAN, M. D. (Brack Shops Building, Los Angeles)—The treatment of tumors of the bladder is a fascinating one. Doctor Ferrier has handled the subject in a very masterly manner.

In dealing with tumors of the bladder, two things have to be remembered. One is that whatever the apparent nature of any tumor that springs from the mucosa may be, if it is not removed and removed completely, early, it will eventually become carcinoma-

tous. The other is, that any method of treatment applied to it must be thoroughly destructive to all of its pathological cells, or it will prove futile.

I am satisfied if the tumor is discovered within a reasonable time after its appearance, that we possess, in its dessication by the skillful use of the D'Arsonval current; by the burial of radium needles within the tissues of the bladder at the site and in the immediate neighborhood of the growth—by the modality of the high voltage x-ray—agents which will, used singly, or with judgment in combination, effect a cure.

I do not look with favor upon any bloody dissection of the tumors. I have removed tumors, even when cancerous, by the knife and, in a few instances, have effected a cure; but resection, combined, as it inevitably is, always with rough handling, is not a reasonable method of treating these tumors, and does not give to the patient a proper chance.

I am inclined to believe that we have, in the recently introduced modality of the radio knife, an agent which will prove very valuable for the gross removal of bladder tumors in a bloodless manner. The dissection made, the base should then receive the application of the fulgurating current, or the placing of radium in needles at the selected spots within the zone of the tumors in the bladder wall, from which they have been removed.

I am not in favor of the proposal to remove the bladder in totality, the benefits of which seem to be an obsession of Doctor Ferrier. It is practically impossible to make a complete dissection of all of the tissues which are involved in the cancerous growth that has invaded the sphincter. Total cystectomy is not an easy operation even upon a man who is dead, and one might be allowed to be very skeptical about the thirty-two permanent cures which are said to have been collected by Scheele. If a carcinoma of the bladder is manifestly inoperable or success has not followed a radical application of the measures herein advocated, a double lateral nephrostomy will be, by all means, the measure which will give to the individual the greatest comfort and the longest life.

R. L. RIGDON, M. D. (291 Geary street, San Francisco)—The attitude of the general surgeon toward neoplasms in any part of the body may be characterized as radical. He realizes from a vast experience, that thorough and complete removal is the only justifiable method to pursue and if any course short of this is recommended, it is because of some deterrent circumstance in the individual case.

I believe this same attitude should be taken by urologists, with reference to bladder tumors; in other words, complete removal or destruction should be the aim.

There are so many conflicting circumstances to be considered in tumors of the bladder that very often the best method of procedure is difficult to determine, and it is just here that Doctor Ferrier's paper holds much of interest for us. He has very clearly and definitely suggested the best modes of procedure in different types of cases and his paper should be a reference guide to us in our work.

Another point that must impress all of us, is the necessity of early diagnosis. All practitioners of medicine, specialists or general, should have impressed upon them the necessity of giving due heed to the early symptoms, such as hematuria. Most patients are much alarmed at the appearance of blood in the urine, but unless this be accompanied by pain, they are apt to attach too little importance to it and presently their natural optimism and distaste for examination lead them to put aside investigation to a later date. In this manner, one golden moment may pass and the trouble which might be controlled easily if taken early merges into that large group of late diagnoses, where remedial measures are difficult or impossible.

FRANK HINMAN, M. D. (380 Post Street, San Francisco)—The paper by Doctor Ferrier brings out clearly and in detail the main and important facts of diagnosis and treatment of tumors of the bladder and I see no criticism of any statements he has made.

It was my privilege to work for three years side by side with J. T. Geraghty who has been the most quoted authority on bladder tumors for the past ten years and who always gave to those about him freely and com-

pletely of his knowledge and experience, and I carry with me today some very important impressions as a result of this association.

In the first place, the presumptive evidences of tumor of the bladder are rarely definite. Bleeding is a sign so frequently in other conditions than tumor and frequency of urination or other disturbances of urination accompanies other conditions even more frequently so that symptomatically can tumor of the bladder rarely be diagnosed. The one and only positive finding, other, of course, than that from cystotomy, is the cystoscopic one, and, clinically, Geraghty was always accustomed to differentiate two distinct types of bladder tumor; the one was papillary and most frequently multiple, the other was a sessile and infiltrating flat type tumor and occurred usually singly. The papillary tumors were distinctly of three types: First, the benign papilloma, second, the malignant papilloma and, third, the papillary carcinoma, the distinction being very simply that there was no cancer in the first, that in the second the malignant degeneration was confined to the body of the polyp and in the third that the malignancy was infiltrating the base and bladder wall, but clinically the three types were conveniently associated because the initial treatment of all three was the same, namely fulguration. The second single infiltrating sessile type tumor comprised the vesical carcinomas in which fulguration is usually useless. The cystoscopic differentiation of these two types is usually simple and it must always be borne in mind that a papillary tumor is potentially malignant even though it is not a papillary carcinoma. Attempts to remove fragments with a cystoscopic rongeur are, as a rule, not of much assistance in the diagnosis between a benign and malignant tumor except when such fragments are definitely malignant; negative findings are valueless for the fact that the fragment may have well come from a benign area.

In a plan of treatment of bladder tumors the above clinical differentiation of Geraghty's is a great help. The initial treatment of all papillary tumors, irrespective of its being any one of the three types mentioned, is fulguration and, according to the immediate responses, the use also of radium and x-ray. One very important factor in the treatment of this type of tumor is follow-up treatment and periodic observation and inspection for long periods after the initial treatment. The next line of treatment in these cases is that of resection surgically after the cautery method of Edwin Beer of New York in all papillary type tumors which do not readily disappear under fulguration, radium and x-ray. In the sessile or infiltrating type tumor the first consideration is whether the tumor is operable or inoperable and this surgical consideration is concerned not only with the amount of mutilation so far as the bladder itself is concerned, on account of its site, but is also concerned with the clinical condition of the patient as to age and surgical risk. If operable under these considerations, radical resection, after the cautery method of Edwin Beer, should be given preference, it always being understood that at the time of operation radium implantation is used and that proper x-ray treatment is given afterwards.

Under this head of operable tumors, I believe, there is a distinct field of usefulness for even the radical one of extraperitoneal cystectomy with suprapubic ureteral drainage as advocated by Judd or, according to the operative conditions at the time, uretero-rectal implantation. In the second inoperable group of infiltrating tumors fulguration, radium and x-ray should be given second choice and cystotomy and nephrostomy third choice as purely palliative measures.

Under the above plan of diagnosis and treatment of bladder tumor, it is seen that the most important factor that will give the optimum result is early diagnosis, and cystoscopy can now be recognized as the one method of making an early diagnosis, so that every case in any way suspicious should be immediately cystoscoped.

Men who cannot be beaten, though they fail a score of times, men who cannot be discouraged by an army of difficulties, sometimes go tumbling down as a result of a little success. More men are failures on account of success than on account of failure.—Dearborn Independent.

CHRONIC BACK PAIN FROM A MECHANICAL POINT OF VIEW

By JOHN DUNLOP, M. D., Los Angeles

Faulty mechanics of the lumbosacral joints are more responsible for backache than are the sacro-iliac joints.

There are very few sacro-iliac injuries which are not accompanied by lumbosacral injury.

A very careful history will usually show that most backaches are initiated by an acute onset.

DISCUSSION by Alfred Roncovieri, San Francisco; Maynard C. Harding, San Diego; William Lisle Bell, Oakland; Harold H. Hitchcock, Oakland.

IT IS always a matter of surprise to me that the importance of faulty mechanism of the spine as a cause of chronic back pain is not more frequently recognized. I say this reservedly, for I appreciate that the specialist is often criticized for diagnosing a condition as falling into the category of his own special line. However, when a certain type of case comes very frequently under the observation of the specialist it is natural that he should be impressed by the importance of a correct understanding of it.

Chronic back pain, from a mechanical point of view, has held the attention of the orthopedic surgeon since Doctor Goldthwait's first paper in 1905, concerning the relation of the relaxation of the sacro-iliac joints to instability of the back. I have been fortunate enough to be in a position to observe the entire development of the subject of back pain from the orthopedic standpoint, and since the early days my ideas have undergone considerable change. I was one of those who (twenty years ago) attributed almost all the backaches to the relaxation of the sacro-iliac joints. For the last twelve years, however, I have felt that faulty mechanics of the lumbosacral joints were more responsible for the trouble than were the sacro-iliac joints, and the more I have been able to study my cases, especially with very carefully made stereoscopic x-ray examination, the more positive I feel that the lumbosacral joints are at fault in the great percentage of cases. In fact, I feel that there are very few sacro-iliac injuries which are not accompanied by lumbosacral injury.

When we take into consideration the spine and pelvis and their mechanical construction, we wonder that these very delicately constructed joints are not more frequently the subject of injury.

We might stop here to explain what we mean by injury. Most of the injuries are of a subtle nature; I should say strains from a disturbance of relations at the joint surface. I mean a relaxation or stretching of the ligaments holding such joints in their normal relationships: by sprains, I mean a definite tearing of tissues, which would allow abnormal freedom of movement. There is no question in my mind but that many of these acute cases, or those with acute onset, are due to sprains. Further, when the relaxation is sufficient, there can be no question about the increased amount of mobility possible in the joints, even to the point of dislocation, and we must feel that a number of these badly contused cases are fractures, fresh or healed.

In addition to injuries, we must take into consideration the diseases which are of a chronic nature and can inflict injury on joints and cause somewhat similar symptoms. Hypertrophic or infectious ar-

thrititis are probably the more responsible causes, but we must remember that we are dealing with true joints in every respect and that they are subject to every disease that any other joint is subject to, and therefore the whole category of possibilities must be considered.

A very careful history will usually show that most backaches were initiated by an acute onset. The patient can almost always say just when the trouble started. In Dr. Goldthwait's early cases, which were those following delivery, the trauma was unquestionably due to the act of child-bearing, and from that time on the patient was conscious of a difference. It is my opinion that in all of those cases connected with obstetrical conditions there are sacro-iliac relaxations or injuries and, no doubt, most of those first cases reported by Dr. Goldthwait were of that nature. There is, undoubtedly, a large class of cases where the relaxation of the supporting ligaments to the sacro-iliac joints is so extreme that true motion exists in one or both sacro-iliac joints. This is especially so in the cases where there is so much difficulty following childbirth.

There is another class of cases belonging in this category to which I wish to draw attention, because they have been little understood. I refer to the cases of women who have backache accompanying the normal or abnormal relaxation during menstruation. This relaxation is, in my opinion, definitely due to the softening of the ligaments supporting the sacro-iliac or pelvic joints prior to, or accompanying menstruation, due to a more copious supply of blood to all of the pelvic structures at such a time; another reason why those so afflicted should remain quiet, in order to avoid strain during this period.

As one's experience grows, it appears more evident that post-parturient or delivery injury forms but a small percentage of the cases under discussion. Persons who are subjected to any activity which places a more than ordinary load on the spinal articulation are liable to this injury. I personally believe that among people who have lived to middle age there are few who have not suffered sufficient injury of some spinal or pelvic joint to have had symptoms therefrom.

The more common symptoms of such a condition are sciatica and lumbago. Victims of these so-called maladies often suffer acutely and continuously, and it is astonishingly difficult to convince most of them that their sufferings can be quickly and completely relieved by a skilful treatment of the mechanism of the joints. We should emphasize our assurance to such patients that prompt and complete relief can be obtained, usually by simple means, and that invalidism is unnecessary. This advice should be disseminated, not only among those who have followed mistaken methods of treatment, but also among that class of industrial cases who, rather than work in good healthy surroundings for a living, seek the existence allowed for disability by our State Compensation laws.

It is quite easy to appreciate the signs and symptoms of low back injury of the lumbosacral area when we consider the lumbosacral joints. They are shallow, about half an inch in diameter, irregular in shape and faceted. It is by means of these little facets that practically all the motion between the

trunk and the lower part of the body takes place. In the ordinary way in which we use our bodies it is easy to understand how strains can take place in this location, because there is so little protection against them.

Papers written in recent years by anatomists establish the variations in anatomy of the low part of the spine and the pelvic articulations. Under such conditions it is difficult what is normal or what constitutes normal function. Many of us feel that the greater the departure from what we have considered normal, the more pronounced and uncertain are the consequences of injury. We do know that most of the understood signs point more often to the lumbosacral or sacro-iliac than to the intervertebral articulation higher up. This conclusion also is supported by our anatomical observations. The joints higher up than the fourth lumbar run pretty close to standard construction and lend themselves very little to joint injury.

It may be well to enumerate some of the possible traumatic injuries: bad posture; that is, any position which will put the lumbosacral or sacro-iliac joints on a strain. Flat back; pendulous abdomen with lordosis; short leg; scoliosis, paralysis, are examples. The former faulty dress of women was often responsible for faulty attitudes; such as improperly constructed corsets and improperly balanced shoes. The harm produced by faulty dress has, with present styles, been almost eliminated, and there has been considerable improvement in shoes, although they still form a definite etiological factor.

Knowledge of the usual antero-posterior spinal curves is necessary in order to be able to judge of lordosis or flat-back, which is so predominant and prevalent in backaches due to postural defects. Occupational injury may be very slight and yet be a factor in producing backaches. The use of the joint in a slightly unprotected position over a long period of time, causing a constant stretching or irritation of the joint may be all that is required. Riding in an automobile in a faulty position is a common example. Sitting in a chair of uncomfortable height; standing slightly stooping in any type of work, or flattening of the back on the operating-table when the patient is completely anesthetized, may produce trauma. These are types of injuries which are unnoticed by the patient at the time of injury.

SLIGHT TRAUMA DUE TO SUDDEN OVER-STRETCHING OF THE JOINTS

This, I believe, is the largest group of causative agents of backache. One suddenly moves in a certain way, or meets an unexpected resistance to motion, there is a stitch in the back and one has difficulty in straightening up, the pain being always located at the lumbosacral area. Examples of this may be very slight or very severe. In former papers I have noted some of the most severe types.

The point I want to emphasize is that we are dealing with abnormal joints, the result, in a great majority of cases, of injury, and that these injured joints are not functioning normally, and that through this abnormality of function certain symptoms develop.

I will enumerate: Backache, with pain, located usually at the lumbosacral level, at times distinctly

down the line of the sacro-iliac joint. On abdominal examination, we frequently find tenderness on pressure over the sacro-iliac joints.

There may be referred pains from disturbance of posture or from nerve irritation. Those from disturbance of posture are usually referred up the spine, especially to the back of the neck, but may be quite bad in the mid-dorsal area. Those troubles from referred pains are usually sciatica, pain in the hip-joint, in the sacro-sciatic notch, coccyx, in the low abdomen and groin, and down the outer side of the leg; pain associated with constipation and filling of the large bowel, causing pressure on the sacro-iliac joints in front; and pain directly associated with menstruation at the time when the pelvic ligaments are naturally softened.

The *physical signs* of mechanical disturbance are: Obliteration of the lumbosacral curve; obliteration of lumbosacral fossae; prominence of sacrum; asymmetry of the lumbar and sacral region; prominence and spasm of the lumbar muscles, usually unilateral; restriction of motion in the low spine; restriction of straight-leg lifting; restriction of hyperextension of the hip-joint; usually *little* restriction of the flexed hip in either direction, or complete flexion of hip; tenderness on pressure over the irritated joints, both from behind and through the abdomen, and also from a rectal or pelvic examination; restriction of all movements producing movement of the low spine, such as arising from bed with legs straight, causing pull of the hamstring muscles; rising from the sitting position, stooping; lying in bed, with too much sag, thereby obliterating the normal lumbar curve, as in long protracted illness and fractures.

In accepting faulty posture as one of the frequent causes of backstrain, we must not lose sight of the fact that disturbed foot balance, by throwing the body out of correct alignment, may be a large factor in the production of backache. The normal relations of weight-bearing surfaces of the joints are disturbed, and mechanical irritation is thereby produced.

Much has been ascribed to the sacro-iliac joints which, I think, could well have been ascribed to the lumbosacral joints. There is a condition due to acute trauma which, to my knowledge, has never been so described. I have demonstrated this both from an x-ray standpoint and by clinical observation. It is a rotation of one innominate bone. For such an injury to take place there must be an accompanying injury of the symphysis and one sacro-iliac joint. In those cases where I believe this to have taken place the amount of rotation is, I believe, very slight, but definite enough to make a distinct difference at the pubis and the ilium and the ilium and sacrum on one side. With very carefully taken stereoscopic rays in more than one plane where the findings are identical, I believe such a lesion can be demonstrated. And manipulation done under anesthesia, with the idea of rotating the innominate bone, produces immediate results, which convince me of the correctness of the observation. With such a manipulation there is the feeling and audible demonstration of a click, and on the awakening of the patient the pain is gone. I have plates which, when carefully examined in a stereoscope, will prove my

contention. Unfortunately, these stereoscopic plates cannot be demonstrated on a screen. This lesion is necessarily a true sacro-iliac injury.

Treatment must be attacked as the treatment of injury in any other joint would be attacked; that is, rest through the acutely irritated stage; restoration of relationship by manipulation or, if necessary, operation of the affected joint; gradual return of function without producing pain, the latter usually with the use of some form of fixation in order to prevent further irritation; local improvement of muscle and ligamentous tone and improvement of local circulation; correction of posture by use of apparatus or physical development.

CONCLUSIONS

I. That chronic back pain is very often the result of disturbed mechanics of the bones and joints of the spine and pelvis.

II. That normally constructed joints of the spine and pelvis, when subjected to extraordinary stress, are liable to injury just as are other joints of the body.

III. That in subjects where the normal tone of the ligamentous structure has been lost unusual movement in the joints is possible and the ordinary stability is lacking, with accompanying strain (of the entire mechanics dependent upon it); or there may even be such relaxation that dislocation may be possible.

IV. That the disturbance of the normal mechanics is frequently due to abnormalities or asymmetrical developments of the spinal and pelvic zones, and more especially due to the formation of the joint surfaces between the spine and pelvis known as the lumbosacral articulations, which lend themselves more readily to injury when subjected to any unusual uses to which they may be put. That unless the mechanical defect is corrected pain remains, due to a true mechanical irritation within the joint. In the cases caused by relaxation the tone of the supporting tissue must be supported and built up to enable them to do their usual work. In the cases where there has been a true change in the relation of the joints, the normal relation must be restored before the supporting and building up process is instituted. In the cases where anatomical construction is at fault, in addition to support during the irritated stage, the patient must be instructed in the use of the body in such a way as to prevent strain and irritation.

V. That most carefully trained physical directors who fully appreciate the work in hand should be employed, and should work wholly under the supervision of the physician.

523 West Sixth Street.

DISCUSSION

ALFRED RONCOVIERI, M. D. (Flood Building, San Francisco)—Doctor Dunlop has presented an interesting paper on an important subject. After ten years of active industrial surgery, I know of no other type of disability which presents such a problematic outcome from the standpoint of response to treatment and recovery. It seems to me, as Dunlop has suggested, that there has been a general lack of understanding as to the mechanics of back strains, as well as the pathology and treatment.

I am particularly struck with Dunlop's summary of back injuries, with particular reference to the finer shades

of interpretation between strains and sprains, which, I think, admirably covers the situation.

I concur with his opinion regarding the likelihood of most low back injuries being lumbosacral rather than sacro-iliac in origin and pathology. Aside from the fact that clinically we can demonstrate this to be true in the majority of cases, it also seems reasonable from a consideration of the anatomy and structure of the region. The lumbosacral articulation is a true joint, movable and exposed to injury much more pronounced than the sacro-iliacs which, anatomically, are not true joints, but synchondroses. I have always felt that it is mechanically almost impossible to get ordinary strains of the sacro-iliacs without some degree of sub-luxation. Luxations of the joint, even in slight degree, can now be positively demonstrated by radiograms which should show a distinct altered relationship of the symphysis.

I am sorry Doctor Dunlop did not go into the matter more fully of operative treatment for true sacro-iliac pathology, both traumatic and non-traumatic. From my observation of patients coming under my care during the past two or three years, and with a review of the literature, I am becoming convinced that a well-performed sacro-iliac arthrodesis by the Smith-Peterson procedure gives the best and most practical means of eventual recovery in these troublesome cases, particularly referring to the definite luxated or diseased types. Though frequently tried, and at times with relief and improvement, manipulation and immobilization rarely seem to have produced the desired results in my hands.

Unquestionably postural deformities predispose to low back strains, and prolong recovery, as Dunlop has pointed out.

The question of a complicating osteo-arthritis is also another disturbing factor, which, in my experience, has always aggravated more severe back strains, and has prolonged the milder types.

MAYNARD C. HARDING, M. D. (Electric Building, San Diego)—Doctor Dunlop's excellent paper opens so many lines for discussion that one must leave out much that he would like to say. Two points are uppermost in my mind.

The first is in regard to x-ray. After ten years of checking up hundreds of cases of back pain with the x-rays of normal cases, I am forced to the opinion that it is rare, indeed, to get positive x-ray findings in sacro-iliac pain. The low lumbar pains give a slightly higher percentage of positives.

The second point is in regard to the technique of examination. I wish that Dunlop had given us, from the fullness of his experience, his exact methods of examination. I believe that most of the poor diagnoses of back pain are due to slovenly methods, and I, for one, am unable to arrive at a diagnosis with any certainty until I have gone through my entire procedure.

A few months ago I visited a large number of orthopedic hospitals in the East, and in not one did I see a back examined with sufficient thoroughness to warrant the diagnosis arrived at. I feel it is for orthopedic surgeons to lead the way in instructing the profession at large in the methods of diagnosis and treatment of these distressing patients who come to us all.

WILLIAM LISLE BELL, M. D. (1327 Broadway, Oakland)—It has been a pleasure to go over the paper of Doctor Dunlop. He certainly knows his subject and I, too, am only sorry that he could not have had more space to devote to treatment. A paper of this sort necessarily covers so much territory that one must conserve somewhere.

As early as 1908 I had convinced myself that lumbosacral comprised the volume of lower back injuries and have even gone so far as to say publicly once or twice that I thought sacro-iliacs constituted not over 5 per cent. So I cannot very well disagree with Dunlop on this score. I am convinced also that, were we able to have patients with back injuries within twenty-four or at the most not over forty-eight hours from time of trauma, with proper distraction, relaxation, and fixation, very few of them would go on to a prolonged chronic condition. Many of them are untreated for years and worse than that, many of them go to the ignorant manipulators who pretend to adjust.

One point mentioned to me by a famous old Vienna physician twenty years ago is intra-abdominal gas pressure, mechanical pressure, with its consequent intestinal toxæmia. As to softening of the sacro-iliac ligaments during menstruation and consequent relaxation, well, I shall have to be a trifle disagreeable and say to Doctor Dunlop that my own view of this angle inclines more to a general edema in this region at this time, with its extension, no doubt, to the somewhat predisposed nerve structures. And then, to my mind, one of the most prolific causes of low grade back discomfort, that type which is more or less continuously present and often quite discomforting during sudden extensive excursions of the spine, is not a muscle spasm, is not an inflamed nerve, is not a disarranged column, but the chronic fibrosis, or better still the chronic inelasticity of certain groups of muscles that have degenerated in their continuous effort at splinting.

These muscles are not often palpable, and do not seem rigid except when distracted by the opposing group, but they do have very limited extensibility and do effect a decided pinching when their elastic limit has been reached through contraction of the counter group. It is in these cases that deep thorough intelligent massage helps, but massage alone cannot relieve this condition without active and oft-repeated stretching on the part of the patient himself.

HAROLD H. HITCHCOCK, M. D. (1904 Franklin Street, Oakland)—The mechanics of the back are certainly a great factor not only in causing back pain, but in keeping on going after it has once started.

In the figures obtained by Roger Lee and Lloyd Brown at Harvard, and the University of California Infirmary, examining freshmen students, it was found that 75 per cent of all male freshmen have very poor body mechanics. If this is true of these young men, the pick of the country, it must also be true of those outside of our colleges.

I believe that long-continued tilting the pelvis forward, slumping the upper trunk backward and hanging the head forward, an attitude of fatigue, gives rise to contractures in the psoas and rectus femoris muscles, as well as other smaller muscles that makes it almost impossible for many people to tilt their pelvis backward and decrease their lumbar curve, just as foot drop gives contracture of the calf group.

The muscle balance in the low back is thereby upset just as a short heel cord will upset the muscle balance in a foot, and much extra work is put on the small lumbosacral joints which should be taken care of by normally balanced muscles. Many of these injuries will not clear up until this balance is restored. I regret that Dunlop could not give more space to his corrective procedures.

Young men who are using their bodies mechanically incorrectly constitute one of the biggest problems at the University of California Infirmary. Their x-ray findings are usually negative, they do not improve until their whole mode of living is corrected, which includes their bed, automobile, their chairs and their way of standing, walking and using their bodies.

I have not been able to visualize ligaments relaxing and stretching as a result of increased congestion of the pelvis vessels.

Curve of Inorganic Blood Phosphates During the Sugar Tolerance Test; Significance in Diagnosis and Prognosis—F. W. Hartman and Adolph Bolliger, Detroit (Journal A. M. A.), assert that the effects of insulin on phosphate utilization are comparable to those on carbohydrate utilization. Abnormal carbohydrate metabolism may be divided into seven groups by means of the blood phosphate curve. Slight abnormalities and the functionless pancreas are readily identified through the phosphate curve. Abnormal carbohydrate metabolism associated with the pituitary, and possibly with the suprarenals, may be recognized.

What do you think about the suggestion that has been made, to make drug addiction a reportable disease?

THE PATHOLOGY OF COLITIS

By CURTIS E. SMITH, M. D., San Francisco

Apart from the inflammatory or destructive lesions produced in the colon by tuberculosis, syphilis, amebic or bacillary dysentery, carcinoma and diverticulitis, there is a heterogeneous clinical group, designated as mucous, idiopathic, infectious, hemorrhagic and ulcerative colitis.

Colitis may be secondary to certain diseases which lower the resistance of the patient with probably some toxic effect on the mucous membrane which allows bacterial invasion.

The disease variously described as idiopathic, infectious or ulcerative colitis is an inflammation of the mucous membrane of the colon, probably due to bacterial invasion.

Discussion by George Dock, Pasadena; J. Marion Read, San Francisco; Rawson J. Pickard, San Diego.

UNFORTUNATELY the pathologist cannot see pathological, chemical, and biological processes in their various phases as they are taking place in the human body. One is often forced to study merely the end-result of such a process at necropsy, which is of scant benefit to the patient. This seems especially true of the inflammatory processes of the large intestine, which may terminate in the condition known as chronic ulcerative colitis.

Apart from the inflammatory or destructive lesions produced in the colon by tuberculosis, syphilis, amebic or bacillary dysentery, carcinoma and diverticulitis, there is a heterogeneous clinical group designated as mucous, idiopathic, infectious, hemorrhagic, and ulcerative colitis. This group is idiopathic, in the sense that no definite organisms or other etiological agents have been found to account for the inflammatory process. Any attempt to separate the various types of colitis in this group into definite clinical entities would seem as illogical as the terms "mucous," "hemorrhagic," or "ulcerative rhinitis." The difference, pathologically, in these various forms of colitis is in the degree of the inflammatory process.

Anatomically and physiologically, the colon is rendered more amenable to inflammatory processes than any other part of the gastro-intestinal tract. The rate of progress of the intestinal contents is directly proportional to their toxicity, but the intestinal bacterial flora are inversely proportional, both in number and in virulence, to the digestive activity. The acid reaction in the stomach and terminal ileum is probably protective in character, and the ileum is rarely involved in the non-specific inflammatory processes which affect the colon. Inflammations are more frequent in the colon where the opportunities for trauma are greatest, owing to the character of the material, to the presence of great quantities of bacteria, and to the fact that the protective elements are directly proportional to the digestive powers. Constipation is probably a great factor in causing trauma to the colon, and the lesions are often most marked in the cecum and sigmoid. Colitis may be secondary to certain diseases which lower the resistance of the patient, with probably some toxic effect on the mucous membrane, which allows bacterial invasion. When the colitis is not a secondary complication of some other disease, it is probably initiated by a change in the chemical reaction of the intestinal contents or a change in the activity and pathogenicity of the intestinal bacteria. In some

patients the opsonic index and agglutination tests show a lowered resistance to the bacillus coli. An additional factor is the fact that the colon may act as an excretory organ, as is shown in the lesions following mercury or lead poisoning, and is suggestive by the frequency of ulceration in uraemia. Flexner found that the toxin of the Shiga bacillus, injected intravenously, caused ulceration of the colon.

The disease variously described as idiopathic, infectious or ulcerative colitis is an inflammation of the mucous membrane of the colon, probably due to bacterial invasion. The actual nature of its genesis is not definitely understood. Sometimes it appears to be grafted on a previous specific dysentery, either bacillary or amebic, where these organisms disappear, leaving an inflammatory process carried on by a mixed infection of the ordinary bacteria in the intestine. Sometimes it appears as a sequel to some infectious diseases, such as measles, diphtheria, influenza, and pneumonia. It may occur in patients with general debility, ill health, overwork, or poor nutrition. On the other hand, a severe fulminating acute type is described as occurring in individuals in perfect health. The disease is remarkable for its remissions, and the intermittency does not suggest a repeated invasion by a specific micro-organism. It may start as a mild catarrhal inflammation, giving the symptoms of the so-called mucous colitis and with remissions become a more severe inflammation with mucus, blood, and pus in the stools. Finally, after repeated attacks with recurrent infection and an attempt at healing progressing simultaneously, this results in the condition known as the chronic ulcerative colitis of Hale White, which is somewhat comparable to a chronic diffuse nephritis, which develops after repeated injury to the kidney, complicated by attempts at repair. When this process is fully developed in the colon it probably can never heal spontaneously.

Occasionally one sees patients who suddenly develop an acute fulminating inflammation of the colon, with marked destruction of mucous membrane and profuse hemorrhage. In this case the patient may succumb in a comparatively short time, due probably to the toxicity resulting from a rapid rate of absorption rather than from the severity of the local infection.

In the differential diagnosis of chronic ulcerative colitis, the following conditions must be considered: (1) Diarrheas, due to faulty assimilation of food; those of nervous origin, and those due to general debility in diseases, such as pernicious anemia, tuberculosis, heart disease, nephritis etc. (2) Carcinoma of the rectum or colon. (3) Chronic bacillary or amebic dysentery. (4) Tuberculous enterocolitis. (5) Diverticulitis. The pathology of the above conditions is well known and need not be considered here.

In the acute stages of colitis the mucous membrane is edematous, dark red, granular or bosselated in appearance. A profuse exudate, forming a pseudomembrane, may be found. The mucous membrane appears to be lifted away from its subjacent structures. There may be no circumscribed ulcers, but the entire mucous membrane of the colon may show a confluent process of erosion. As the acuteness diminishes, the mucous membrane is less edematous

and covered by irregular patches of exudate. Between the patches are irregular oblong ulcers, varying in size and depth, with overhanging edges and worm-eaten bases. If the inflammation subsides the mucous membrane becomes pale, and certain areas separated by an arterio-venous network, gives to the bowel a checkerboard appearance. It retains for some time its granular character and bleeds easily if touched. In chronic ulcerative colitis the lesions are usually most marked in the rectum and sigmoid. Here the mucous membrane may be almost completely denuded, leaving a granular, bleeding surface and marked thickening and fibrosis of the wall. In other parts of the colon various stages of ulceration may be found. The mucous membrane becomes adherent to the muscular coat and loses the elasticity of motion characteristic of a normal bowel. If the inflammatory process is severe, deep ulcers going on to perforation may develop, but in this condition only a localized and not a generalized peritonitis usually results. One of the chief characteristics is the extreme thickening of the wall of the colon with smoothing out of the folds, leaving a glazed surface. This marked thickening is first due to hyperplasia, edema and infiltration in the mucosa, and later to fibrosis in the wall. Later, contraction of the fibrous tissue may result in a marked narrowing of the lumen, which, if localized, may result in partial obstruction. It is an interesting fact to the surgeon, if a stoma is made proximal to the infection the strictures will disappear and function will result, even when patients have multiple fistulous openings to the outside.

A multiple polyposis is apt to develop in chronic cases, due to localized hyperplasia of the mucous membrane. This condition may cause some annoyance to the surgeon when he attempts to close a colostomy. The appendix has received more than its share of suspicion in these conditions; it often shows an inflammatory process similar to and probably always secondary to the colitis. The ileum is practically never involved. The histopathology is perhaps more variable than the gross pathology, yet it presents merely the simple picture of acute, sub-acute or chronic inflammation, depending upon the stage of the process. The mucous membrane and subjacent structures are usually involved. Congestion and edema may be limited to the mucosa, sub-mucosa, or may involve the entire intestinal wall. The mucosa may be covered with an exudate composed of pus cells, bacteria, and inflammatory elements. It may be devoid of glands in case necrosis has progressed. Lymphocytic and plasma cell infiltration of varying degrees may involve the mucosa or the entire colon and its peritoneal covering. There is usually marked fibrosis with thickening of the wall, but areas may be found where the wall is almost reduced to the thinness of tissue-paper.

The other organs of the body show nothing of any significance in relation to the colitis. The fact that patients with chronic ulcerative colitis retain their weight and are healthy, except for the colitis, shows a negligible amount of toxic absorption, as compared with certain acute cases. Perforation, with localized peritonitis and paralytic ileus, is probably the most common cause of death.

DISCUSSION

GEORGE DOCK, M. D. (Chamber of Commerce Building, Pasadena)—Doctor Smith describes one kind of pathologist, but there is another kind—the physician who deals with sick people and who should have the foundation furnished by pathology. In his mind's eye he tries to see the processes taking place in the human body. From his training at the autopsy, on the living body or post mortem, he keeps active his criticism and knows how he may be wrong, but he and his patient with some form of colitis, both profit from this habit of thinking in terms of pathology. This kind of physician does not abuse his mind by calling diseases idiopathic. He uses classifications merely as a convenience and he may gain by using the one Smith gives, but he keeps his etiological sense active by constantly working on the causes or conditions of disease. By doing that, Kartulis, Flexner, and others added to our knowledge, as others may do in the future. This sort of doctor does not think that the whole "difference of the various forms of colitis is in the degree of inflammatory process," as shown by such diverse conditions as a well-marked mucous colitis on the one hand and a chronic non-anemic process on the other. This sort of a doctor will profit by the efforts of others to clarify knowledge or stimulate thought, including the essay of Doctor Smith.

J. MARION READ, M. D. (Flood Building, San Francisco)—Doctor Smith has performed a very useful function by his endeavor to elucidate the pathological conditions found in colitis. From a clinical viewpoint we would have preferred he had separated his material into two classes, representing the acute and chronic types, for the clinical picture differs considerably in the two conditions. In the acute form it is probable that bacterial infection plays the chief role; in fact, is the causative agent, and the accompanying clinical and pathological picture is one of an acute infection. It is the chronic form which the average internist sees most often, in fact, quite frequently. This rarely follows the acute type, but is insidious in its onset, and most obstinate in its response to therapy. It seems probable that infection plays a secondary role to mechanical factors in these cases. A good, working classification of colitis is much needed, and a pathological study may afford us one, but the subject is a difficult one upon which to obtain material for study, as colitis is so infrequently a cause of death.

RAWSON J. PICKARD, M. D. (Watts Building, San Diego)—It is, unfortunately, true of cases of chronic colitis that, after exhaustive searches for specific or for unusually virulent organisms, there is a large residue of cases with unknown etiology for which the term "idiopathic" covers our ignorance. Smith's paper is valuable in pointing out the area yet to be explored. His suggestion as to the chemical nature of these cases, even the possibility of injury from the excretory function of the colon, may lead to discovery.

Perhaps analogy will assist us in a conception of the causation and treatment of these cases. Chronic flagellate infections are often encountered resistant to all the many antiparasitides which are cleared up by a change in the chemistry of the intestine through diet, with or without the feeding of bacterial cultures. Empiric treatment indicates that the basis of persistent flagellate infection may reside in an obscure biochemical state. Whether, in colitis cases, a pathogenic flora, acquired virulence of normal flora, or the chemical habitat from the diet precede, is of less moment than the result. Of course, with the destruction present in old cases of colitis there can be no return to normal.

DOCTOR SMITH (closing)—I am sorry that the pathologists have not had the opportunity to demonstrate to Doctor Dock lesions in the colon that are as characteristic as the clinical symptoms in the different types of colitis. In a case that we have just studied, the patient clinically had "mucous colitis" at intervals over a period of twenty-six years and finally died, presenting the characteristic clinical and pathological picture of chronic ulcerative colitis. I wish to emphasize the fact that the gross and microscopic appearance does not begin to explain the etiology of these types of colitis, but merely shows a difference in the degree or stage of the inflammatory reaction. Bacteriological studies have also failed, so we must look further. Realizing this, I do not sponsor the idiopathogenesis of any disease.

RECOGNITION OF SURGICAL DISEASES OF THE GALL-BLADDER

By CHARLES S. JAMES, M. D., *Los Angeles*

I believe firmly that the typhoid and colon bacilli are the chief instigators of gall-bladder disease.

I further hold that all cases of gall-bladder disease are primarily medical cases.

The belief was formerly prevalent that "latent gall-stones" cause no appreciable disturbance; but it is now recognized that they rarely fail to produce symptoms commonly referred to the stomach.

We should not accept the diagnosis "nervous dyspepsia," "acute indigestion," "neuralgia of the stomach," "gastritis" or "gastric neurosis" so frequently as we do in patients presenting the history of dyspepsia of a chronic resistant type.

DISCUSSION by James A. Mattison, *Soldiers' Home, Los Angeles County*; Sterling Bunnell, *San Francisco*.

THE various surgical diseases of the gall-bladder and ducts will be better understood if we consider and accept the underlying etiological factor to be infection; that the infection is of hematogenous transmission through the portal vein or hepatic artery; and that the reaction of the infection primarily is in the walls of the gall-bladder.

I firmly believe that the typhoid and colon bacilli are the chief instigators of gall-bladder disease.

I further hold that all cases of gall-bladder disease are primarily medical cases with the possibility of complications developing or arising of a surgical character, and after surgical intervention and the correction of the surgical phase, the patient again becomes medical in the sense that the individual should be under competent management and observation until a complete maintained re-establishment of health is had and not discharged as cured immediately upon making "an operative recovery," as is too often the case.

If we accept the primary etiological factor to be bacterial, it is easier for us to account for the diseases of the gall-bladder presenting such a wide range in their degree of severity and persistence; and the occurrence of varied surgical complications with the element of too frequent apparent failure following surgical intervention, due to the uncorrected underlying and continuing infection; i. e., cholecystitis or cholangitis.

It is then almost entirely the complications and sequela of this underlying disease that constitute the surgical diseases of the gall-bladder and ducts, the most frequent of which are chronic resisting cholecystitis—cholelithiasis—suppurative cholangitis and empyema of the gall-bladder. Carcinoma of the gall-bladder and ducts is increasing in its recognized frequency.

The belief was formerly prevalent that "latent gall-stones" cause no appreciable disturbance; but it is now recognized that they rarely fail to produce symptoms commonly referred to the stomach—sudden attacks of indigestion with flatulence at irregular intervals, oftentimes nocturnal, with indefinite right-sided tenderness, or slight distress referred to the right shoulder and variable degrees of acholia. This group of hazy subjective symptoms may characterize a type of "stomach trouble" occurring years before.

The diagnosis in many instances rests more on the

thorough careful painstaking history than upon any other one factor. In a case of "chronic dyspepsia" characterized by pressure distress, accumulation of gas in the upper abdomen, eructation and sour regurgitation occurring promptly after eating a heavy meal or some special food, epigastric distress radiating to the back or the tip of the right shoulder-blade (Boas' area), history of attacks of acute indigestion with or without a colicky phase, and with or without varying acholia, one is strongly inclined to the opinion of gall-bladder disease origin and recall the trite saying of our clinical forefathers, "Fat, fair, and forty."

Boas' point tenderness and pain referred to the right back are common and valuable symptoms, but we must recognize their occurrence from other lesions than gall-bladder disease, and also that this pain is sometimes referred to similar locations on the left side. I mention this fact because the profession is educated to exclude gall-bladder pathology when pain is referred to the left.

Gall-stones may be present for years and recognized for the first time on the operating table or at autopsy. "Latent gall-stones" constantly pass recognition, and it is only when associated with the varied degrees of activated cholecystitis or cholangitis that they are considered.

We should not accept the diagnosis "nervous dyspepsia," "acute indigestion," "neuralgia of the stomach," "gastritis," or "gastric neurosis" so frequently as we do in patients presenting the history of dyspepsia of a chronic resistant type, and we should remember that all these cases occurring during the third and fourth decade, or later, with a preceding period of immunity, in general, suggest gall-bladder disease, or possibly cardiorenalvascular disease, or carcinoma, and is worthy of our most exhaustive investigation.

In order to definitely diagnose disease of the gall-bladder, one requires more than a history of reflex gastric symptoms; he must, by examination, determine localizing symptoms, such as the colic of cholelithiasis or the pain and tenderness of cholecystitis or cholangitis, and it is here that we must rely largely on the older diagnostic measures.

Distention and tenderness in varying degrees constitute probably the most constant clinical localized expression of cholecystitis. The distention is determined by the varied forms of palpation. A palpable gall-bladder is usually a pathological one, usually moves with respiration and is movable only in a small segment of the circle, the center of which is at the point of the gall-bladder attachment at the external tip of the ninth costal cartilage. Tenderness is best elicited by deep thumb or finger-tip pressure maintained during complete respiration and expiration or "respiratory arrest test." A test for tenderness that I have found quite reliable is similar to the stroke test of Murphy for kidney tenderness, but is applied in a similar manner anterior and just over the tip of the ninth rib, with the patient either in the supine or sitting position; which, if positive, causes a sharp decisive pain with its origin in the gall-bladder.

Jaundice is a variable symptom in gall-bladder disease; obstruction at the first or second portion of the cystic duct will result in no jaundice; if

in the terminal portion, there may be a variable amount of jaundice, depending on the amount of pressure upon the hepatic or common duct, or the degree of associated cholangitis present. With obstruction in the common duct, jaundice may vary, for obvious reasons, from slight and transient to persistent and severe.

Again, we may have the so-called ball-valve acting stone in the common duct with associated paroxysmal chills, fever, and sweating (*Charcot's fever*) simulating empyema of the gall-bladder. But with persistent variable jaundice, bile is seldom absent from the duodenal contents in common duct-block unless the cause is carcinoma.

In suspected cases of gall-bladder diseases the urine should be frequently tested for trace of bile; for slight degrees of obstruction, not causing observable jaundice, sometimes show a trace for a short period. The examination of the stool is of value in evidencing gross acholia, more minutely determined chemically by the Schmidt bichloride test, and by laboratory methods may prove of value in aiding in the differential diagnosis of amoebic abscess of liver, membranous colitis, occult blood of ulcer or carcinoma, etc.

The radiologic examination is of value largely by exclusion of ulcer and carcinoma of the stomach and nephrolithiasis. It is true that occasionally brilliant positive results are presented in showing calculi or the presence of confirmatory indirect signs as duodenal cap indentation, adhesive distortion, or visible gall-bladder, but in general it may be said that an affirmative report is highly valuable but a negative report valueless. There is no such thing as exclusion of gall-stones by radiology.

Graham and Cole describe the phenoltetrabromophthalein test for radiologic visualization of the gall-bladder which, if clinically proven of definite value, gives promise of opening up a field of great diagnostic possibilities. The salt injected into a vein is excreted almost entirely into the bile, helping the gall-bladder to cast a shadow upon the roentgen-ray plate, recording its shape, size, and contained stones if present.

Indicative of the relative occurrence of gall-bladder disease, Blackford and Dwyer of Seattle, reporting a study of 1650 patients complaining of chronic dyspepsia, state: "The approximate relative frequency of abdominal organic disease causing dyspepsia in this series is: Gastric ulcer, 1; gastric carcinoma, 2; reflex appendix, 4; duodenal ulcer, 6; gall-bladder disease, 12"—or nearly one-half due to gall-bladder disease.

This report closely parallels my own observation and conforms to the experience of many other clinicians and should serve to stimulate our interest in the law of probability when surveying our cases of "dyspepsia" of occult origin.

In considering the differential diagnoses, the gastric diseases—ulcer, carcinoma, and syphilis—are but few in number, compared to the many extra gastric lesions producing symptoms masquerading as diseases of the stomach, for the "stomach is the alarm-clock of the human system."

A carefully taken history and thorough physical and radiologic examination usually serves to make clear the diagnosis of the intrinsic gastric lesions

hereinabove mentioned; but it is with the extra gastric lesions that we find confusion and concern.

Digestive complaint may constitute the chief complaint associated with remote systemic disease, such as pulmonary tuberculosis, grave anemia, chronic pancreatitis, cardiorenalvascular disease, pelvic pathology, appendicitis, stone in the kidney or ureter, and many consultants have seen cases of tabes not relieved of their crisis by a preceding operation upon the gall-bladder.

The physical examination should serve to exclude pulmonary tuberculosis, grave anemia, cardiorenalvascular disease and other systemic diseases associated with digestive symptoms.

Among the colic-causing diseases we may cite that in chronic pancreatitis symptoms may not differ from those of gall-stones, and the two often co-exist. The pain, however, is more apt to be in the mid-line or referred to the left of the upper abdomen—more weight loss and the laboratory may show diminution of pancreatic enzymes.

Acute hemorrhagic pancreatitis is attended with greater collapse and rectus rigidity.

Floating kidney, with Dietl's crisis, may present urinary signs and a more movable tumor, both poles palpable and the maximum mass to the back, as compared to gall-bladder maximum to the front.

Nephrolithiasis, by the pain radiating to the pelvis and thigh, vesical irritation, urinary findings, no jaundice.

Carcinoma of the head of the pancreas presents tumor fixed and deep, loss of flesh, profound continuing jaundice, with enlargement of gall-bladder. Carcinoma of the pancreas, gall-bladder, or pylorus can be excluded, however, at times with great difficulty; nevertheless, tumor cachexia and ascites when present speak strongly for carcinoma.

The diagnosis of acute appendicitis may present considerable differential difficulties, especially if the appendix lies high or Riedel's lobe be elongated. However, the pain reference is different and rectal examination may serve to make clear the situation.

As regards the gastric symptoms reflex from the appendix, it is noted that the reflex gastric symptoms of gall-bladder disease occur promptly in ten to thirty minutes after food intake, while if of appendical origin the time elapsed is more like that pertaining to gastric or duodenal ulcer—two to four hours.

In closing I may mention a group oftentimes presenting special differential diagnostic difficulties as suppuration complicating common duct stones, empyema of the gall-bladder, necrosis and rupture with hepatic abscess, or perforation with peritonitis, all of which present gross evidence of gravity and may be classed under the medical slang phrase, "acute surgical belly," which calls for prompt surgical intervention.

Westlake Professional Building.

DISCUSSION

JAMES A. MATTISON, M. D. (Soldiers' Home, Los Angeles County)—My discussion on Doctor James' very excellent paper will be very brief.

Since all of our gall-bladders removed at operation are sent to the pathological laboratory for complete examination and report, there is no longer doubt in regard to the fact that the chief etiological factor is bacterial in origin, the infection entering the biliary tract either by direct

extension or through hematogenous or lymphatic channels. Notwithstanding that great progress has been made in diagnostic methods, it still remains a fact that the most important part of our diagnostic information is derived from a careful study of a thorough history of the case.

In making a differential diagnosis of gall bladder disease, gastric and duodenal ulcers are among the conditions which call for the most careful consideration. Here, again, we find a carefully taken history of first importance, and in differentiating the intra-gastric diseases the most important aid which we have at our command is the x-ray. This gives us definite information in from 90 to 95 per cent of cases of gastric ulcer, provided it is in the hands of an expert roentgenologist. It is generally conceded, however, that the x-ray in gall-bladder disease furnishes confirmatory evidence rather than definite evidence. From our experience, I have found a careful study of the gastro-intestinal tract with a large series of x-ray plates is likewise of value in the diagnosis of gall-bladder disease, aside from the information furnished of intra-gastric conditions.

In our study of gall-bladder conditions, it is necessary to constantly keep in mind the fact, too, that the association of peptic ulcer and cholecystitis and chronic appendicitis is comparatively common and, in a certain number of cases, may be the cause of considerable confusion, especially where two or even three of these conditions are associated in the same patient.

STERLING BUNNELL, M. D. (Physicians Building, San Francisco)—The ideas expressed in this most commendable paper appeal to me as the true conception of cholecystitis. Instead of thinking in terms of gall-stone disease and recognizing only veteran cases, we are learning to recognize infections of the gall-bladder in their incipency.

We now know that the infection is not limited to the gall-bladder, but is generalized in the biliary tract, through the gall-bladder ducts, pancreas, accompanying lymph glands and liver, and that it usually results from germ bombardment coming from infections in the portal system.

Removing the principal focus, the walls of the gall-bladder, by cholecystectomy, together with the original source of infection, if still present, usually cures, but for the following reasons it is not surprising that it does not always do so:

Several months to a year or more are necessary for the natural protective forces of the body to rid the rest of the biliary tract of infection, and especially so if deep-seated infection exists in the head of the pancreas or liver. Again, time is necessary for normal function to return in a stomach which has acquired the indigestion habit. Frequently enough after cholecystectomy the resulting adhesions pull on the pylorus or trigger-point of the stomach and cause a persistence of symptoms. Avoiding trauma in operation and routinely anchoring the end of the omentum in the duodenal-hepatic angle helps to prevent this.

Often tiny stones and sand in the common duct are overlooked, as it is impossible to palpate them through the duct walls. These cause a backfire of infection into the liver and continue the symptoms.

Disease of the gall-bladder makes its presence known to the clinician largely by a perversion of stomach functions, by general symptoms of infection, by disturbances of bile flow, by pain from duct obstruction, by pain, distress and tenderness from local infection in the gall-bladder.

The normal-acting stomach should handle the usual articles of diet and, if it does not, an organic lesion is often the cause. It is unsafe, though, to yield to our desire to simplify and assume that all dyspepsias are caused by the arch triumvirate, appendicitis, cholecystitis and peptic ulcer. When we consider what a multitude of diseases affect our outer covering, the skin, a tissue that we can see, we cannot but admit that our inner lining, the digestive tract, may also be subject to many different ailments.

However, when a patient tells of years of indigestion and of submission to prescribed diet lists and digestive aids, the real cause can usually be found in one or more of the above triumvirate. If the indigestion is

qualitative, intermittent, gradually increasing in severity and length of attacks and accompanied by symptoms of infection, both general and local, in the region of the gall-bladder, this organ comes decidedly under suspicion.

It is, however, only after a survey of all other symptoms, x-ray findings, physical signs and past history, and a due consideration of other possibilities, that we can arrive at a judgment of the case of sufficient value to advise surgical relief.

THE REFLEX NERVOUS DISORDERS AS DESCRIBED BY BABINSKI

By A. R. TIMME, M. D., Los Angeles

Sets up a group of nervous disorders which may not be classified as either functional or organic by usual methods. One case report.

These patients exhibit symptoms far more profound than could be accounted for on a functional basis, and yet not typical of any of the so-called peripheral or central lesions.

DISCUSSION by Harold W. Wright, San Francisco; Samuel D. Ingham, Los Angeles; Edward W. Twitchell, San Francisco; Thomas J. Orbison, Los Angeles.

WE HAVE long been accustomed to labeling as functional any case of paralysis that did not show classical symptoms of definite organic lesion of the nervous system. Thus, localization and grouping of signs indicated to us whether a lesion was in a peripheral nerve, in a plexus, spinal root, spinal cord, or anywhere up to and including the cortex, or in an artery, or in the meninges. Any case of paralysis or deformity that would not fit into any of the above molds was very likely to be classified as functional or hysterical.

There is, however, a group of cases, definitely organic, that do not fall into either of the above categories, i. e., these patients exhibit symptoms far more profound than could be accounted for on a functional basis, and yet not typical of any of the so-called peripheral or central lesions.

Although not explaining the pathology of the lesion, John Hunter, as early as 1835, called attention to muscular atrophy following joint affections, e. g., arthritis. Charcot and Vulpian in the eighties first predicated a reflex origin of such atrophies. Babinski, in the beginning of the Great War, finally gave us an adequate description of this type of lesion, in the form of papers, discussions, and an elaborate monograph. He terms the condition "nervous troubles of a reflex order" or "reflex nervous disorders" and postulates a reflex pathogenesis in certain cases of paralysis, contracture and deformity, atrophy, sensory and vasomotor change following wound or injury of an extremity that do not conform to any of the classical conceptions of central or peripheral lesion of the nervous system or to hysteria. Thus, an almost negligible wound of an extremity can give rise to profound changes in muscular tone and activity, can produce a disproportionate amount of atrophy with vasomotor and sensory disturbance, or it can produce a marked deformity or contracture. These changes cannot be explained by any of the known nerve, cord or brain lesions; they remain in a stationary or progressive state for years after the initial wound or injury has healed.

Prerequisite to the development of the above symptoms is the initial trauma or irritation, whether

an arthritis, a fracture of a long bone, or a gunshot wound. If a gunshot wound, it involves bone or soft tissues without injuring a nerve. Symptoms develop immediately after the injury or months later. They are out of all proportion to the severity of the injury, and in this respect resemble hysteria. They seem to disregard anatomical limits, but may be said roughly to appear in the same or adjacent spinal segments as the initial trauma. The following groups of symptoms are encountered:

(1) Muscular atrophy with paralysis. The atrophy is usually less marked than that of neuritis or anterior poliomyelitis and the paralysis only partial. It may involve single muscles, groups of muscles, or the entire extremity. The paralysis is of the flaccid type.

(2) Contractures and deformities. A few typical contracture deformities are described by Babinski, e. g., contracture of the pelvi-trochanteric muscles following traumatism in the region of the hip, producing a typical "salutation gait"; flexion contracture of the leg, in which the heel remains raised both in standing and walking; various types of club-foot and claw-toes; numerous forms of contractures of the hand and fingers, including the typical "accoucheur's hand"; hypertonus of the flexors of the hand associated with hypotonus of the extensors, producing a strong wrist-drop deformity; and many others.

(3) Vasomotor and temperature changes. The affected limb is blue and cold and responds to air or water temperature variations more slowly than the sound limb. It may also be mottled and reddish and pit on pressure. Arterial pulsations may be weaker in the affected member and the oscillations of decreased amplitude. Obstinate coldness of the hand or foot is the rule in cold weather.

(4) Hyperexcitability of the muscle to percussion, together with slowness of the muscular contraction resulting, are described by Babinski. On striking the belly of the affected muscle with a small percussion hammer, a contraction of great amplitude is produced, which is sustained longer than normal. Babinski has demonstrated this graphically.

(5) Loss of muscular tone may be pronounced in the affected muscle groups. Thus the thigh may be hyperflexed on the body, with the leg extended, or with the leg itself hyperflexed on the thigh, producing an exaggerated letter "Z."

(6) Electrical changes. There may be increased response, i. e., contractions of increased amplitude to both galvanic and faradic currents, or there may be a corresponding hypoexcitability. Babinski also describes premature fusion of contractions to the faradic current. True R. D. is never present.

(7) Changes in reflexes. Tendon reflexes are normal or exaggerated on the affected side. Sometimes the exaggeration can be demonstrated only while the patient is anesthetized.

(8) Sensory changes are inconstant and may assume the form of a hyper or hypoesthesia, frequently of a segmentary distribution. Spontaneous pain in the affected area is also frequently encountered.

In differential diagnosis the chief source of trouble is hysteria, since these cases do not conform to the symptomatology of any of the known anatomical

lesions. A valuable aid in establishing a diagnosis of reflex disorder is examination during chloroform anesthesia. In this state the tendon reflexes become definitely exaggerated on the affected side, attempt to correct the deformity causes muscular spasm, and the contracture persists to an advanced stage of the narcosis. These signs are not true of hysteria. The deformity of reflex disorders also persists during sleep. Other differences are as follows: The paralysis in reflex disorders is more limited in extent and more persistent; the deformities do not correspond to any natural attitude as they do in hysteria; atrophy, vasomotor, and trophic changes are more

marked in reflex disorders; changes in muscular tone are more pronounced than in hysteria; electrical reactions and reflexes are normal in hysteria, but affected in reflex disorders.

Differentiation from organic monoplegia and from peripheral neuritis is easier, since it calls into play our knowledge of anatomy and nerve distribution. The well-known Babinski reflex is never present in these cases, nor are any of the typical signs of upper-motor-neurone lesion. The location of pain, wasting of muscles, R. D. and correlation of motor and sensory symptoms serve to distinguish a peripheral neuritis.

Volkman's ischemic paralysis and Dupuytren's contracture sometimes produce deformities similar to those of reflex disorders, but the muscular induration and lack of electrical reaction in the Volkman lesion, the nodular change in the palmar skin and fascia in the Dupuytren lesion serve as valuable diagnostic points.

As to pathogenesis, Charcot first postulated a reflex origin of the atrophy incident to an arthritis—a peripheral irritation of centripetal nerves in the joint by the inflammatory process, causing an irritation of the anterior horn motor cells, with a resultant atrophy. This reflex arc is called into play in the cases under discussion, Babinski maintains, and so not only furnishes a rational explanation of causation, but also includes these disorders in the organic category. As yet, however, actual histologi-

cal change in the anterior horn cells has not been demonstrated.

PROGNOSIS AND TREATMENT

Since reflex disorders are an undoubted organic condition, psychotherapy has no place in their treatment, except insofar as hysterical symptoms are superimposed. Babinski reports improvement following gentle massage and movement and continuous extension. He cautions against violent and energetic means which are likely to increase the deformity by causing further irritation of the reflex arc. He reports favorable results with mild applications of heat and diathermy. Certain heroic measures have been tried, such as alcohol injections into nerves, excision of the scar tissue of the initial trauma, a destruction of the periarterial plexuses of sympathetic filaments, all with more or less indifferent results.

CASE REPORT

W. R. W. Age 40. Received a through and through wound of the left wrist by a machine gun bullet in December, 1915. The bullet entered the dorsum of the wrist near the head of the radius and emerged from the palmar aspect near the base of the last metacarpal. No infection occurred and the scars are at present barely visible. A plaster cast was applied the following day and remained on about three months without causing any undue discomfort. The cast extended from the base of the metatarsals half-way to the elbow. Flexion contracture of the fingers began almost immediately following the injury, and when the cast was removed the fingers were half closed. This contracture has been progressive to date, in spite of the application during 1917 and 1918 of a large palmar splint designed to maintain the fingers in extension. The flexor pull of the fingers against this splint caused marked pain.

Today the last three fingers of the left hand are so tightly drawn against the palm that the distal ends of the middle phalanges bid fair to crowd through the skin of the fingers. There is beginning slight erosion of the skin of the palm. The third and fifth fingers override the fourth. Forcible extension of the fingers away from the palm is impossible to an extent greater than one inch. Motion at the wrist, of the thumb and index finger is practically unimpaired. There is slight atrophy of the hypothenar eminence. There is one-quarter inch atrophy at the wrist and one-half inch at the forearm. Other movements of the upper extremity are unimpaired. The tendon reflexes are equal to those in the right arm. There is no R. D., in fact, response to the faradic and to K. C. C. is even more prompt than in the right forearm. Direct muscular excitability is about equal in the two forearms and in the two thenar eminences. There is no sensory change. There is obstinate cyanosis and hypothermia in cold weather and after immersion in cold water. There is, at such times, decreased amplitude of the radial pulsations.

General physical and neurological examination is otherwise negative.

Other conditions to be considered in this case are: (1) ulnar neuritis, since the ulnar side is chiefly involved, (2) Volkmann's ischemic paralysis, (3) Dupuytren's contracture, (4) hysteria. Ulnar neuritis is ruled out by absence of typical atrophy and sensory change. Volkmann's is ruled out by absence of muscular induration and presence of electrical reaction. There is no evidence of hypertrophy of the palmar fascia or ridging of the skin of the palm, such as is seen in Dupuytren's disease. As to hysteria, it is inconceivable that a deformity of this severity or duration could be entirely functional. Furthermore, the positive vasomotor changes, the gradual progression of the deformity during eight years, the unnaturalness of the deformity, i. e., the

impossibility to assume the position voluntarily, all point to an organic affection.

Brockman Building.

DISCUSSION

HAROLD W. WRIGHT, M. D. (Flood Building, San Francisco)—This paper is an important contribution as a clear summary of these forms of peculiar syndromes, following peripheral injury and because it calls attention forcibly to the features which distinguish such disorders from hysteria. The word "reflex," as applied to such symptoms and pathological conditions, is, to my mind, not very satisfactory. Nervous reflexes of manifold and peculiar nature, producing symptoms of disordered function at a distance from the place of origin of the reflex activity, we are familiar with, but such reflex disorders are disorders of function and not of structure, i. e., not lesions. In the conditions described in this paper we have definite pathological changes of tissue resulting from something besides a mere irritation of function. May it not be that in some of these disorders there has been an unrecognized infection of the end plates of motor nerve filaments, a localized neuritis at first, then irritative reflexes resulting, and possibly an ascent of the infective or toxic process to anterior horn cells with resulting irritation of other reflex paths at that level?

SAMUEL D. INGHAM, M. D. (1920 Wilshire Boulevard, Los Angeles)—The diagnosis of the conditions here presented offers much difficulty, since it is well established that certain of the functional cases, with local paralysis and contractures develop tissue changes, including joint fixations and rarefaction of bone, as secondary results. On the other hand, indefinable organic and toxic conditions may affect the physical integrity of the nervous structures without producing clean-cut signs or symptoms. We frequently see atrophy of muscles that have been subjected to prolonged reflex rigidity, and that is apparently the conception of Babinski in regard to these cases.

It is impossible to say, in view of our present knowledge, whether there may not be, as Doctor Wright suggests, an absorption of toxin or even actual infection of the peripheral nerves with sufficient resulting disturbance of the innervation to explain the symptoms.

EDWARD W. TWITCHELL, M. D. (909 Hyde Street, San Francisco)—The word "reflex" is very unsatisfactory to describe the condition, and it is curious that Babinski, with his genius for naming symptoms, did not devise a name free from the old associations inseparable from "reflex." He was alive to the possibility of the role that the autonomic system might play in these cases and spoke of it in his monograph. That seems to me to be the most nearly adequate explanation for the present. If a causal-gia be the expression of the sensory manifestations of sympathetic diseases, why may not this irritation extend to the trophic and motor fibers of the same system? Why is a contracture in the case described not due to stimulation of a reflex arc contained entirely within the system of sympathetic fibers efferent and afferent?

The paper is important in that it jars us out of our dimensional attitude toward nervous diseases and brings to our notice another dimension to which others will, no doubt, in time be added.

THOMAS J. ORBISON, M. D. (2007 Wilshire Boulevard, Los Angeles)—I do not disagree with the diagnosis made by Timme in this very interesting and well-presented case. On the contrary, I am inclined to concur in it. But there are two or three points that need to be cleared up. One is that this man has never been subjected to chloroform anaesthesia—at least no mention has been made of this. It would seem to me that this would give the real clue that would enable a correct diagnosis.

The other point is that I noticed that quite a marked extension could be obtained when, in my examination of the patient, moderate, but sustained traction in extension was made on the fingers. This seemed to tire, and I noted a more or less rhythmical attempt at maintaining the original posture, which attempts came with less force at the end of the short time I made traction. A third point should be borne in mind, namely, that his hand remained in a splint for three months. In my opinion

this man should have been anesthetized quite early in order to make diagnosis certain.

DOCTOR TIMME (closing)—The strongest criticism encountered by Babinski, when he formulated this concept, was from those who clung to the hysterical explanation for such cases as these. But in this case hysteria would be a diagnosis by elimination, rather than a positive one. We have all been too prone to call a thing functional if it does not fit into the known organic pictures. After all, the tendency of medical research is to increase the number of "organic pictures."

Among many wounds of extremities in American troops, I have encountered only two of these cases, whereas the French found them with much greater frequency.

I have been unable to find any pathological reports whatever, but I have no doubt that some alteration in structure will be seen somewhere between anterior horn cells and motor end-plates.

The sympathetic fibers are, no doubt, always involved, as shown by the vasomotor and trophic changes. But there is no evidence as yet that striped muscle has any sympathetic innervation, or at least that sympathetic stimuli can produce striped muscle spasm.

This man had moderate and sustained traction by means of splints for nearly two years, but the deformity persisted and advanced. This speaks for a powerful irritative factor at work. A splint deformity does not act this way.

Let us keep this concept of reflex disorder in mind. Perhaps many doubtful and borderline cases can, in the future, be so explained.

A Clinical Classification of Bright's Disease—Thomas Addis, San Francisco (Journal A. M. A.), made a study of the effect of various physical factors on the formed elements of the urine. He found that hyaline casts and all casts whose matrix was hyaline disappeared from neutral sodium chlorid solutions when the salt concentration was reduced to less than 0.5 per cent. When the hydrogen ion concentration of the solution was varied, it was observed that the less the hydrogen ion concentration the greater was the concentration of sodium chlorid necessary to keep the casts from dissolving. He had already noticed that those specimens of urine in which few or no casts were present were either dilute or alkaline or had both of these properties in lesser degree. It seemed likely, therefore, that variability was no inherent characteristic of cast formation, but might be the result of changes in the degree of dilution and reaction of the urine. This proved to be the case, since the variability was replaced by a satisfactory degree of constancy whenever the conditions were such as to induce the secretion of concentrated and acid urine. The results of the examination of the urinary sediments of the patients who were investigated fall, naturally, on qualitative as well as on quantitative grounds, into three main divisions; and since these divisions seem to be corroborated by many significant facts elicited by other methods of examination, Addis has become persuaded that they represent three diseases that are pathologically and etiologically distinct and separate. In order to avoid the confusion that would result from the use of terms that are familiar but have been used with a somewhat different meaning, he has reverted to a purely descriptive terminology and has called the first division hemorrhagic Bright's disease (seventy-one cases), the second degenerative Bright's disease (forty-three cases), and the third arteriosclerotic Bright's disease (twenty-six cases). The initial stage is a sequel of streptococcal infections. The second disease has been called degenerative Bright's disease because the constant and most prominent feature of the sediment is the large number of apithelial cells in various stages of granular or fatty degeneration. The third disease, arteriosclerotic Bright's disease, is of great importance because it occurs more frequently than any other form of Bright's disease. But so far as the kidney is concerned, its importance is of a negative character; for when the diagnosis has been made it is no longer necessary to consider the renal lesion as a factor in the management of the patient. These are the patients with hypertension who are often told that they are suffering from "chronic interstitial nephritis" and who consequently live in fear of death in uremia that never comes. These conditions are described in detail.

Clinical Notes and Case Reports

UNUSUALLY EXTENSIVE INJURY

REPORT OF A CASE

By S. M. SPROAT, M. D., Portola, California

A. O., age 22. Mill laborer, single, was brought to the Sierra Valley Hospital at Loyalton July 28, 1925, suffering from avulsion of the entire scrotum, skin, and subcutaneous tissues of the entire penis, abdomen, and left side, with testicles entirely denuded, and lying on the abdomen. The patient had been caught in the live rollers of the mill at 7:45 a. m., and was bleeding profusely and suffering profoundly from shock when seen at 10 a. m. in consultation with Dr. W. A. Lavery of Loyalton. Pulse 135, weak, thready; blood pressure, systolic, 90.

The patient was at once removed to the operating-room, anesthetized, and the entire area scrubbed with a scrubbing-brush and tincture green soap and water, after which sterile water was poured over the entire area. The testicles were placed in an artificial scrotum formed

by flaps from the inner sides of the thighs. The flaps were united in the midline with sutures of silkworm gut, leaving the perineum resembling that of a female. The penis was repaired and covered with skin drawn back from the foreskin which covered the distal end of the penis and which had escaped injury. The proximal end of the penis was covered with skin which had been avulsed from the abdomen and placed around it in a spiral manner. This graft did not live. The abdomen was covered, to a large extent, by bringing in large skin flaps from the surrounding healthy skin, and also by one large flap, which had been torn off. The skin which had been avulsed did not live, nor was it expected that it would live at the time of operation, but it was thought advisable to cover as much raw area at this time as possible on account of the likelihood of this lessening, to some extent, the marked shock which was present, and it evidently served this purpose.

For about ten days the patient had a stormy conva-

lescence, but after two weeks was out of danger and making a nice recovery. The photographs were taken August 20, and upon August 29 an extensive skin graft was done by Dr. Lavery and myself by the Thiersh method. This has taken well for the most part, and the patient is well on the road to a complete recovery.

This case is of interest because of the extensive injury, of which the pictures give only a small idea, and from the fact that recovery was made after such an injury involving such a tremendous area and severely injuring the testicles, scrotum and penis, and producing severe shock.

CONGENITAL CYSTIC KIDNEY

A CASE REPORT

By WALTER PRITCHARD, M. D., Colton, California

J. M. B. Teacher, single, age 40. In October, 1923, complained of cramps in the right loin for five days, with fever, headache, and vomiting.

One sister had a "cystic kidney" excised during her forties; the diagnosis was made after operation. Another sister, now in her fifties, is pale and puffy in the face, but repeated urine examinations fail to confirm the suspicion of nephritis.

For twenty years the patient had had attacks of colic in the right loin, with belching, bloating, headache, and fever, lasting a few days and occurring a few months apart. Between the attacks he had diffuse headaches. Fifteen years ago he bruised the left loin in a fall. He had "meningitis" twelve years ago. For several years, ending five years ago, he had "pyelitis and nephritis," a systolic blood pressure of 200, and took urotropin daily.

P. E.—The patient was of average weight and development; temperature, 98.4; pulse, regular 80; blood pressure, 140/90. There was marked tenderness in the right loin and less on Murphy maneuver; no psoas spasm; peristalsis was active. There were 16,000 white cells, with 83 per cent polynuclears. The urine was slightly acid, clear amber, 1.018; showed a heavy trace of albumen, trace of indican, a few hyaline-granular casts, and a moderate number of red, white, and renal cells. A tentative diagnosis was made of right pyelitis and nephritis, probably an exacerbation. With rest, local hyperemia, forced fluid intake, and urotropin gr. 15 q. 4 hr., the patient became comfortable within a few days. He refused cystoscopy.

During the next year and a half the patient was seen in several attacks, and the investigations made are here summarized. He finally consented to cystoscopy, which yielded a conclusive diagnosis. Because of the fragmentary development of these investigations, chronological treatment seems better replaced with topical consideration.

Symptomatology—Pain in the loin had harassed the patient for twenty years. It had been in the right side until the past year, and then worse in the left loin. In character it suggested "a lighted candle burning in my side all the time," with cramps during the height of the attack. The pain did not radiate, and was not influenced by voiding or defecating. Nausea and vomiting, malaise

and diffuse frontal headache were frequent. There was frequently a chill and febrile rise to 102, and rapid drop within a few hours. The attacks occurred at any time, beginning rapidly and lasting for hours or days, and were of varying severity. The intervals decreased from months to weeks, and even days. Gross hematuria was never seen. Nicturia once was habitual, but large amounts of urine were never passed.

Subsequent physical examinations revealed constant tenderness in both flanks, becoming exquisite during attacks. A mass was first noticed in March 27, 1925, continuous with the liver to percussion and palpation; it was firm, smooth, slightly tender, reaching downward in the right half of the abdomen to the level of the umbilicus. The sharp lower edge moved with respiration, and was continued in a rounded, firm superficial mass at the right rectus border, suggesting a distended gall-bladder, and measuring two inches across. This mass can be seen in the x-ray of April 5, 1925. A month later the topography had changed: a firm, smooth, tender mass three inches in diameter lay in the midright lower quadrant and moved with respiration, but could not be displaced. The liver edge could be felt just under the ribs. Immediately after cystoscopy, and with the bladder drained, the pa-

No. 1

The x-ray of April 5, 1925, shows the left kidney shadow with a faintly scalloped external border, and upper pole covered by gas in the stomach. The right upper abdomen is occupied by a shadow of uniform density extending from the diaphragm to the level of the umbilicus, and from the midline to the lateral abdominal wall.

tient voided two quarts of urine, and this mass moved four inches cephalad.

Cystoscopies—One on April 5, 1925, indicated a normal bladder, except for slightly enlarged median prostatic lobe. Normal ureteral ostia emitted turbid urine at an average rate. A No. 6 catheter easily passed to the left pelvis, but would not drain, although readily admitting water. The left pelvis admitted 12 cc. of 20 per cent sodium iodide solution, with pain characteristic of the attacks. The right ureter readily admitted a No. 5 catheter, and drained urine at an average rate. It was not thought wise to inject both kidneys at the first sitting.

On May 6, 1925, both ureters were emitting turbid urine; catheter to left pelvis, but stopped at pelvic brim in the right side. Both dropped urine rapidly. The left

side admitted 35 cc. of injection fluid readily, with pyelogram as shown. The right catheter, unfortunately, slipped out in removing the cystoscope. But the shadow of the right kidney was so plain that further examinations did not seem necessary. After intramuscular injection, phthalein appeared in twelve minutes from the right side, and in nineteen minutes from the left side.

X-rays—The pyelogram of April 5, 1925, shows the left pelvis only partly distended, with those calices shown, blunted. The pelvis is six inches long, and the kidney shadow about nine inches long by four and a half inches wide, and extends from the dome of the diaphragm to within an inch of the iliac crest. The "liver" shadow is shown, extending downward with uniform density to a sharp lower border at the level of the umbilicus. The gall-bladder region was normal in espe-

No. 2

The x-ray of May 6, 1925, shows the left kidney as before and with the large, imperfectly filled pelvis and calices. The right kidney occupies the corresponding position. Both are deformed above by gas in the stomach and colon.

cially taken x-rays. The x-rays of May 6, 1925, show the left pelvis better distended, and the same blunted calices. The outline of the right kidney is clearly shown in the corresponding position and size, only an inch lower, reaching the iliac crest. This shadow is felt to be the right kidney because it corresponds in size and shape and position with the known left kidney; because the mass markedly shrank and moved cephalad after copious voiding; because of the varying position of the mass in the right side of the abdomen; and because a sister had a cystic kidney removed.

Laboratory Data—A twenty-four-hour urine specimen was 2500 cc.; neutral; 1.010; and contained 2 per cent of albumen. On other occasions there were a few pus cells, hyaline and granular casts, and a few red and renal cells. Non-protein nitrogen 34 milligrams for 100 cc. blood. Wassermann test of the blood was negative. A complete blood examination showed nothing abnormal.

Diagnosis—Bilateral congenital systic degeneration of the kidneys.

Treatment—The patient was placed on a cardio-renal regime, and given a ptosis corset with kidney pads. It was hoped thereby to prevent kinking or rotation of the pedicles. His fluid intake was to be over 3000 cc. daily, and the urine to be kept acid six days a week; and

urotropin gr. 5 taken bid. During three months, he has been free of pain, fever, or headache, and has gained fifteen pounds. Operation was discouraged because both sides were equally involved, and neither side badly infected. The bizarre masses, without typical signs of hydronephrosis (except once), were confusing. The familial character of the disease is illustrated.

TREATMENT OF OTITIS-MEDIA

By B. C. DAVIES, M. D., Los Angeles

In the treatment of this particular condition, both the anatomy and the nature of tissue involved demand special consideration.

Anatomically, we have a semi-closed cavity which communicates with at least two other cavities, while the part involved is relatively minute in area and difficult to reach.

The mucous membrane lining is sensitive and affords a fertile field for infection; moreover, it quickly reacts to irritants, or stimulants, and is capable of producing granulation tissue very rapidly. These findings render treatment difficult and uncertain of results under regulation procedure.

Boric-alcohol instillation goes very little farther than the opening through the tympanum, while the resultant deposit of boric acid impedes both drainage and continued treatment. Phenol-glycerine is no more satisfactory, except in early open cases.

Irrigations, of whatever nature, which contain water do not entirely pass the tympanum, but instead stimulate granulations, which eventually close the tympanic perforation and a chronic otitis-media is established, succeeded frequently by a mastoiditis.

Gentian violet, mercurochrome, acriflavine, and the rest of the newer antiseptics act well on bacteria that are reached, but their progress into the middle ear is easily impeded.

Following its successful use in other purulent conditions, I have for the last year been using pure ether in the treatment of acute and chronic otitis-media, with unvarying success, in over 125 cases. A few case histories follow:

1. Jenny C., age 8. Admitted March 13, 1924. Diagnosis, diphtheria. Acute mastoiditis, left. No operation. Both ears discharging. Boric irrigations. Phenol-glycerine. Treatment lasted five weeks, no improvement. Ether treatment started April 16, 1924. Ears dry, April 30, 1924.

2. John C., age 17. Diagnosis, measles. Ears discharging two weeks before admittance. Had been irrigated since discharge began. Ether treatment started February 13, 1924. Ears dry, February 18, 1924.

3. Mrs. W. J. E., age 47. Post-scarlet otitis-media, left. Ear had been discharging for week. Dry swab, followed by mercurochrome; no results. Ether treatment started March 25, 1924. Ear became dry April 3, 1924. Several cases practically similar cleaned up in one week.

4. James McC., age 7. Scarlet fever, otitis-media, left. Discharge began April 12, 1924. Ether treatment started same day. Dry ear April 20, 1924. Approximately fifteen cases of similar histories showed equally quick results.

5. V. W. M., age 5. Diagnosis, scarlet fever. Ears discharging three days before entry, April 7, 1924. Simple mastoidectomy, right, April 8, 1924. Wound and middle ear washed with ether at time of operation. Canal dry and wound clean, April 15, 1924. Wound healed in less than three weeks. Several cases of the same kind had been irrigated for weeks. Others had been treated with various dye solutions without success.

The technique followed was a careful swabbing, using small cotton swabs, made up fluffed on the

end. A twisting motion removed all pus in the canal and on the tympanum. Then the canal was filled with ether and that ear held uppermost while the ether evaporated. This treatment was given twice daily. In cases of very heavy discharge, the ether treatment was increased to three times daily. Upon the introduction of the ether, there is a transitory stinging which lasts but a few seconds.

The patients vary in age, from 9 months to 45 years. Five cases of wet ears, in post-operative, radical mastoidectomies that had discharged for six months following operation dried up inside of ten days, following the ether treatment.

The points of advantage in using ether are: First, its capacity to penetrate into corners and through very small apertures, as found in granulation tissue areas. Second, does not stimulate granulation tissue. Third, and most important, its rapid solvent action on lipoids, as found in pus and bacteria. No untoward results were noticed in any of the patients treated. Four post-scarlet, early mastoiditis cases were carried through without operation. However, the treatment is not suggested in lieu of operation.

In contagion wards of county hospitals, health office rules require a dry post-scarlet ear before release of the patient, and it can easily be seen that, all other considerations aside, the financial saving to the county by the early release of a large number of patients is considerable.

"Where There Is Darkness There is Disease"—"Printers' ink floods the darkest places with the light of intelligence," writes Dr. Frank Crane. "It is printers' ink that has scared the food fakers. Only at a good round of printers' ink will the vile, carrion flock of unclean birds that fatten on human credulity and ignorance take flight, they that sell plaster of paris for bread, carpenters' glue for candy, and God knows what vileness for fish, flesh, and fowl. Printers' ink has spread right ideas of sanitation, upset old, mildewed superstitions, opened windows, lured people outdoors, flooded fearsome brains with truth, and despairing hearts with hope. It has built hospitals and supports them. It has prevented epidemics, driven hush-mouth authorities to activity in remedial measures of cleansing. It is well enough to give an individual epsom salts or calomel, but what the public needs for what ails it is plenty of printers' ink. The best part of the science of medicine is that part which can be told in plain language so that the common man can understand. Every newspaper ought to have its health department edited by an intelligent physician. What people need to know is the truth about health, about food, and about simple living. The more truth they know the less useless and harmful food they will eat, and the less they will run after religious cure-alls and crazy fads."

Pyelonephritis Complicating Pregnancy After Nephrectomy—John E. Hall, Nashville, Tenn. (Journal A. M. A.), reports the management of a case of pyelonephritis occurring in a woman who became pregnant about one year after he had performed a nephrectomy on her for pyonephrosis of the left kidney. The right kidney was at all times free from infection during her illness from the left-sided pyonephrosis. Attention is called to this fact, so that it may not be supposed that the pyelonephritis developing during pregnancy was due to impairment of the right kidney from infection at the time of this pyonephrosis. The primary focus of infection responsible for the pyelonephritis could not be ascertained. The patient's tonsils were removed shortly after her nephrectomy, and her teeth and accessory sinuses were in perfect condition.

EDITORIALS

THREE YEARS OF THE CORNELL PAY CLINIC

The Cornell Pay Clinic, says its recent report, "has proved a successful demonstration of the possibility of providing good medical service on a self-supporting basis for persons of moderate means. Since these persons constitute the majority of the population, the Cornell Clinic announces itself as 'a demonstration of considerable public importance.'"

The most amazing feature of the expensive report gotten out by these promoters of department-store practice of medicine is that they are apparently proud of the fact that they can successfully compete with private doctors with the "majority of the population."

Their report announces with apparent gusto that, whereas other pay clinics, some of which are enumerated, do serve some poor people free, the Cornell Clinic absolutely refuses charity because it was feared the Clinic would be "swamped by non-paying patients" unless service was "limited to those who could pay its fees." *In other words, this clinic is in the practice of medicine for fees precisely as are private physicians.* They are so cold-blooded about it that they refuse any help to the poor "except in emergencies" and for purposes of "medical education and research." This, of course, gives them a tremendous advantage over the private physician who considers it his duty—and privilege—to render a large amount of free service. It even gives this corporation form of medicine advantages over the Mayo Clinic, the clinic in connection with the Ford Hospital and others they mention, in that all of these do some free work. Cornell claims a large volume of business, with an average of 18,000 new patients a year. The report shows 118,711 visits during 1922, 110,235 during 1923, and 114,705 for 1924. These, according to the report, represent about 90 per cent of those who apply for service; *the other 10 per cent are refused because of inability to pay the fees.* There is another 10 per cent who, although of doubtful financial standing, are accepted.

A Promising Business Venture—Although only in its fourth year of business, this clinic has grown financially from a deficit of \$46,000 in 1921 to a self-sustaining basis in 1924, and the indications are for a substantial profit for 1925, unless some of the usual business methods of preventing such showings of profits are utilized. This is an encouraging showing, from a commercial standpoint. It is said to have taken Mr. Gary longer than this to make United States Steel a paying proposition.

Fees—The report gives the average fees paid by patients as \$2.24 a visit. As an *average*, such fees ought to make the practice of medicine very profitable, particularly when it is remembered that they render no free service. Less than 20 per cent of the doctors of California—and we suspect of New York as well—*average* as much as \$2.24 a visit in the practice of their profession. But, of course, they all

do free work, and most of them a large amount of it, which naturally pulls *their* average down.

Substituting salaries for fees to physicians gives corporation practice of medicine another advantage in their competition with the private fee basis of pay usually employed by the physician who practices as an individual. The Cornell Clinic report shows that they paid \$90,770 as medical salaries last year. When this is considered in connection with the 114,705 patient visits, we see that they paid their doctors the bargain-counter figure of seventy-eight and a fraction cents a patient visit. Mind you, these were no "let me see your tongue" visits. Some 10 per cent of them were first visits, with a "thorough physical examination" which required "nearly three-quarters of an hour of the doctor's time," while the others were revisits requiring "ten or fifteen minutes" of the doctor's time. The report shows that the Clinic paid "non-medical salaries" equivalent to well over a dollar per patient visit. Compare that with the 78-cent doctor's fee, and draw your own conclusions. The report's apology for the "flat fee," like all similar apologies, whether emanating from a Detroit hospital, a labor union, or a government bureau, makes illuminating reading.

The various clinic "chiefs" are paid a "flat salary" of \$1500 a year, which, according to the report, is for from 268 to 360 hours of their time—at most, \$5 per hour. Other doctor employees are divided into two groups—one class is paid \$2 an hour, and the other \$2.50 an hour. They work in clinic "sessions" of two and one-half hours each, and if the doctor finishes his work in two hours he is permitted to take the other thirty minutes off, presumably on full pay. The Clinic attempts to provide these doctors working for wages all the clerical and technical help they can use, but, says the report, "where the physician is supposed to be giving his time in hospital or clinic without remuneration . . . he can be clerk as well as doctor," because this combination "saves the institution money."

In answering the question of who are their patients, the report says the average wage of the patients is \$1800 a year, and that the wage-earners average "somewhat" more than one per family. The report quotes the figures of the Housing Commission of New York, to the effect that two-thirds of the families of the city have incomes under \$2500 per year. Therefore, says the report, "*Potential Cornell Clinic patients represent a majority of the population of the city.*" If this dream should come true before the inevitable awakening occurs, there would be left to the some 15,000 doctors—many of them Cornell graduates—a clientele of a minority of the people of the city, and *all* of the poor would be in this minority because the Cornell Clinic refuses to serve them, so the personal doctor must do so, as he always has done. Interesting, isn't it? That interest will be intensified by the well-bolstered statement of the Clinic that many of their patients "have had previous medical care without satisfactory results before coming to Cornell." We wonder if the Cornell service is so superior that their shoe might not fit the other foot with equal certainty. The report certainly indicates strongly enough what the Cornell Clinic promoters think of

themselves, as compared with their own graduates with whom they are competing, when they say in effect that the great popularity of the Clinic is due to "previous unsatisfactory experiences" of their patients and to the "prominence" of the Clinic doctors, who are "leading members of the medical profession." Considerable space in the report under review is occupied in explaining, by invidious comparisons, how and why the services of the Cornell Clinic "indicate a much higher level of medical efficiency" than do similar figures from other clinics. Some ingenious philosophy and some queer figures are used to support this conclusion, which some readers will extend to a logical conclusion of interesting if not entertaining portent.

To make the claim that because many patients are added to the Clinic's happy clientele because of dissatisfaction with their former doctors is indicative of the Clinic's superior service, is likely to have another side. Surely, there must be some patients—and we suspect there are many—who also became dissatisfied with the Clinic and took their patronage to a clinic competitor. Of course, the ethical doctor works at a disadvantage in this phase of competition because his idea of service does not extend to follow-up letters and personal solicitation to return by paid agents or solicitors of any kind. His contractual relations with his patient are purely personal and wholly voluntary at every stage of the contact.

The authors of this ingenious report appear to get considerable satisfaction out of invidious comparisons of the costs of service to the patient between what they are pleased to term the "commercial rates" of private doctors and their department-store prices. This part of the report reads much like advertisements published for the purpose of increasing trade, and closes with this: "From the financial standpoint, there is no question that the Cornell Clinic is offering a grade of medical service which would be far more expensive to its patients in private offices" . . . and "the family incomes of the Cornell patients are typical of the majority of the families of New York City."

Careful reading of this report of the Cornell Clinic, only a few outstanding features of which have been noted here, leaves the thoughtful reader with a variety of feelings. One is in wonder as to how many of the fifty odd thousand patients who visited the Clinic needed hospital care, including surgical work; what hospitals and what doctors were they sent to? Why? What were the expenses and who paid the bills? The chances for referred work from a large clinic that does no free work and claims the majority of citizens of New York as its legitimate customers ought to be exceedingly great.

The House of Delegates of the American Medical Association has twice disapproved as unnecessary and inadvisable, movements which appear to offer only part of what this clinic offers under similar principles and tending in the same obvious direction.

Are department-store methods and corporation practice of medicine to replace the personal service of the doctor to the patient who chooses him? We wonder. If the policies and practices of the Cornell

Clinic are sound, then many other varieties of big business medicine are sound and in the best interests of the public health. None of these activities can be considered to be local. Attempts to start Cornell Clinics have already been seen in California and presumably elsewhere. If the Cornell Clinic is the best method of caring for thousands of pay patients of New York City annually, then the principle should be extended to all classes of people throughout the country. If it is unsound, unwholesome and unwise, then physicians should say so now, and say so in no unmistakable terms.

HOSPITALS AND THE CULTISTS

Certain groups of inadequately educated "healers," acting under the protective constitutional cloak of religious liberty, have succeeded thus far in having themselves widely admitted to be "above the laws" regulating the practice of the healing art. Certain other groups of ignorant or inadequately educated healers have succeeded in California and certain other places in having the laws so modified as to allow them to license themselves to practice medicine and otherwise assume the responsibilities once the sole prerogative of specially educated professional men and women. These "doctors above the law" and "doctors by law," instead of by education, are now active in further efforts to get control of health services by invading hospitals, laboratories, public health services, clinics, etc., again using politics, legislation and law, instead of education, as the weapons for their offensive. They apparently do not wish their own hospitals for their own purposes, *because there is no objection to this*, and it seems fair to assume they are afraid of the consequences of full responsibility that operating their own hospitals would entail. They want to crowd themselves into hospitals operated for and by educated physicians, and force—by law and politics—these educated physicians to work with them as "fellow practitioners." In a word, they want the safe cloak of intelligence to produce the shadows they require to "get away" with the consequences of their ignorance.

These "sciosophists," as Doctor David Starr Jordan has grouped them in BETTER HEALTH MAGAZINE, find their best opportunities to destroy hospitals as agencies of scientific medicine among those operated by government and in the miscalled "community hospitals," better named "political hospitals."

These are the weakest links in the hospital chain. Of the some forty county and municipal hospitals in California, less than ten are even considered important enough to list. It is exceedingly doubtful if the "sciosophists" could make poorer excuses for hospitals out of most of them than they now are, and the inevitable reaction that must come before the hospitalization of the poor is upon even a decent basis might be hastened by turning the majority of county hospitals over to the "sciosophists" *exclusively*. Such action cannot, of course, be recommended, but if it occurs, as has already happened in part in a few instances, what is now a perpetual disgrace might become a tragedy of such magnitude

as to jar public opinion from its complacency and too obvious indifference.

Of the small minority of acceptably operated county hospitals, "sciosophistic" efforts to burrow in must certainly be resisted. They are making a lot of noise on the cellar doors of—for example—the San Francisco and Los Angeles county hospitals. In the latter they have already secured "rights and privileges" that have placed the standing of that great hospital in jeopardy as an approved agency of scientific medicine and better health. Some of the other county hospitals are even less fortunate.

A most interesting situation is just developing in Santa Barbara county, where steps have been taken to build at Santa Maria a branch of the existing county hospital, and this branch hospital is to be "wide open"; which means that it will be, except in emergencies, an exclusively cult hospital supported by public funds. Of the misnamed "community" hospitals, the stories of efforts at Riverside and Long Beach, now familiar to readers of hospital literature everywhere, ought to prove more effective than has been the case in checking efforts to extend the application of this stupid idea. The shock troops of "sciosophy" are collecting about some of the State government and even National government hospitals, waiting and watching for an unguarded entrance. But by far the most tragic incident that has happened was the *repudiation* by plebiscite of the terms of acceptance of the gift of a memorial hospital by Colonel Simon J. Murphy to the people of Whittier. The story of this debacle has been so often and widely told that it needs no repetition here.

Fortunately, the great majority of hospitals are still in full control of intelligent persons and groups, who are not even tainted with "sciosophy" and are not likely to be. These include the more than half of all hospital beds operated by the Sisterhoods of the Catholic church; most, but not all, of those operated by other church organizations; most of those operated by philanthropic groups of one sort or another; practically all those operated by physicians; and the majority of those conducted by corporations and business organizations. Fortunately, also, the law gives to hospital directors and trustees *absolute authority to decide who may and may not have the privilege of practicing in their institutions*.

This is the most effective bloc that the "sciosophists" have to face in their campaign for hospital control. But they do not consider it hopeless and are working along three lines to overcome it. One sustained effort is to gradually change the controlling personnel to one more friendly. Another is to encourage any and all movements calculated to extend political regulation of hospitals; and another is to promote actively the "community hospital idea." The "sciosophists" know their political power and if they can get government supervision extended, or get hospitals to use in some way—any way—public funds, they believe their chances will be better—and they would be. One of the most interesting of these movements is the sustained effort to have hospitals declared "*public utilities*" and regulated accordingly. We took a long step in this direction when the present, in certain respects commendable, Department of Public Welfare Law was passed by the last Legislature, with jokers in it calculated to

plague every ethical hospital and other health agency in California in the not far distant future.

WHAT CAN BE DONE?

From the political angles, legislation and law enforcement, probably not much. Much recent legislation is immature and faddish; politics has become too much a matter of "bloc juggling" and law enforcement as a whole is at a remarkably low ebb. "Sciosophists" of the near doctor groups, while their more than fifty-seven varieties fight among themselves, seem to have little difficulty in presenting a united front to legislators, voters and other factors of "democracy in action." Opposed to them in this broad field are the intelligenzia, with every fellow holding to his own brand of treatment and opposed to any form of mass action. In that most effective of all power—moral influence—honesty, intelligence, and decency, still have the trump cards. Of these, one of the most effective is the widely accepted ethical ruling that educated doctors, nurses and other recognized health workers may not consult with, work for or with, or have anything whatever to do with any members of the "sciosophy" groups. True, some do violate the principles of their profession by doing these things, but they are well known, both to their colleagues and to much larger groups than they realize. These "twilight zoners" often slip over entirely and become unspeakable. It is from this group of intellectual backsliders that the "testimonials" for fake cures by "celebrated specialists" are recruited. It is from the same groups that "death certificate signers" for "sciosophists" come, and it is from them that leaders of new cures, cults and what not, are recruited.

The moral web was immeasurably strengthened when the American Medical Association, the American College of Surgeons, the American Hospital Association, and practically all other great health serving bodies, extended their restrictive ethics to include hospitals, clinics, and all other agencies of health as well as persons.

A hospital, for example, in order to have any sort of recognition, must limit those permitted to practice in it to persons of certain educational attainments and certain standards of morality. By the same token, a doctor who practices in a hospital with lower standards thereby becomes unethical and is out in the open for what he is. We gather from many letters and inquiries upon this subject that the simple facts are not as well known as they should be, and in order to further clarify and impress the subject, the following abstracts are made from recent letters from the Council on Medical Education and Hospitals of the American Medical Association; the American College of Surgeons, and the American Hospital Association to this editor and to certain hospitals (which shall be nameless) in California:

American Medical Association to W. E. Musgrave:

"The only policy to pursue from now on is to stand fast in the requirement that no hospital will be approved under any circumstances unless it confines membership on its staff to reputable practitioners who have received the degree of Doctor of Medicine from medical schools approved by the American Medical Association and that this ruling must apply

to every person permitted to treat or prescribe for the sick in the hospital. This means that no concessions for any irregulars or incompetent practitioners shall be made whether they hold the M. D. degree or not. I feel certain that you will be in full agreement with such a stand."

American Medical Association to — Hospital:

"The provision for such irregular practitioners in a wing of the hospital cannot, as I believe you will readily see, enable you to entirely separate the various services whether they be professional or non-professional, and the hospital will necessarily have to bear the same name whether it applies to the medical or irregular practitioner division. Indeed, there is no way in which the identity of the two portions of the hospital can be kept separate. *Under no circumstances can the approval of the American Medical Association be given to the practice in hospitals of any individuals, whether they have the degree of Doctor of Medicine or not, unless both educationally and morally they are qualified to intelligently and efficiently care for sick and injured people.* More serious still, however, is the legal status which will result from the arrangement you have made for irregular practitioners—a legal status which you can hardly afford to assume. The board of trustees which controls a hospital, and this refers with particular force to hospitals caring for pay patients, is legally responsible for any errors or malpractice on the part of any practitioner who is permitted to treat the sick in the hospital. *Therefore, that board will be liable for any disasters which may result through the ignorance or incompetence of the irregular practitioner.*

"If the arrangement you have made for irregular practitioners continues, I do not see how recognition can be given to your hospital, either as a place in which efficient care to its patients can be assured, or as a place where an adequate training of interns can be provided.

"The irregulars are fighting against the requirement of reasonably high educational standards throughout the country, but it seems that *they are at present focusing their action on the institutions in the fair state of California.* I believe you will agree with me that the greatest safety to your hospital from every point of view rests in your standing firm for the principles and educational standards which the American Medical Association is trying to uphold in the hospitals of this country."

American College of Surgeons to W. E. Musgrave:

"I want to thank you for your communication of July 6 with enclosures re conditions at the — hospital.

"I have notified them that in view of the action they have taken their standing, so far as the American College of Surgeons is concerned, is endangered. I have, however, asked for an official statement from the hospital authorities regarding their present relations to the irregulars, pending my final decision. I want to get something from them in writing. However, we have sufficient data on hand to cause us to eliminate them from our list of approved hospitals unless there is a very radical change in the near future in the present situation.

"I find that the — and the hospital at — are both playing with the irregulars, and for that reason, particularly, have been notified that we cannot give them our approval.

"— county hospital will soon have their irregular unit ready. *This will disqualify them also, so far as hospital standardization is concerned, inasmuch as this unit is under the corporate name of the hospital which we approve as a whole and not in part.*

"If county hospitals, by virtue of their nature, are obliged to submit to public or popular whims, then I feel that the county hospital system is not a sound one for future hospital development.

"If the medical profession would absolutely refuse to use hospitals which are courting the irregulars

it would settle the matter in a very definite manner, for the hospitals cannot get along without the educated doctors and their clients."

American Hospital Association to — Hospital:

"Your first vital mistake was made when funds were solicited from the public on the presumption that irregular practitioners would be given equal privileges with doctors of medicine. If this is true it would be far better to raise additional funds to repay those who contributed under these representations rather than attempt to run a hospital with the two under one roof.

"So far as this association is concerned we do not recognize a hospital whose staff admits any of the cults. We believe that a hospital is a place for the scientific care of the sick and that the trustees are *morally and legally responsible* for the application in the institution of all of the modern methods and practices generally recognized by the medical profession. We believe that the trustees have an absolute right, and are legally obligated, to choose the members of the staff and that in making such choice they should be bound by the highest standards that have been set in the country.

"I can conceive of no method whereby a decent hospital can permit osteopaths, or other cults, to practice under its corporate name while keeping faith with the public and maintaining high ideals and, because of this belief, we refuse to accept a hospital as a member of this association where such practitioners are admitted.

"It is realized that you have a practical problem to solve and that there exists considerable public sentiment in favor of the cults in your vicinity but we are convinced that only grief and disorganization can result from the sacrifice of fundamental principles and that your only salvation lies in making a determined stand for the right. *If the osteopaths want hospitals let them establish them and go to the public boldly for their funds rather than hide under the cloak of the profession of medicine whose ideals they would destroy.*

"I see no prospect of a compromise when such involves the sacrifice of the things we have so long fought for and I feel safe in saying that this association is not likely to lower its standards through the clamor of a very small minority that is endeavoring to obstruct the wheels of progress."

I might quote more at length and from additional sources, but surely enough has been said to clearly outline the issue between adequate education and morality on the one hand and the hosts of "sciosophy" on the other, at least insofar as hospitals are concerned. A similar problem is forcing itself to the front in the conduct of "clinics," the duties, responsibilities and ethics of nursing and a score or more contacts between agencies of health based upon intelligence and the machinations of the hosts of "sciosophy."

A STUDY OF SURGICAL DIAGNOSTIC ERRORS

The most accurate check yet devised to determine the errors of physicians in their clinical judgment as expressed in diagnoses is, to compare the clinical findings with the autopsy findings in a series of cases. This has been done repeatedly in various centers, but not as often as it should be.

Several months ago (January) we noted in these columns the interesting study made by Sison and Sison from the medical records of patients of the Philippine General Hospital, Manila. More recently, C. M. Reyes (Journal of the Philippine Islands Medical Association) has made a similar comparative study of the clinical and post-mortem

records of the fatal surgical cases of the same hospital during the past twelve years. This study, says the author, is an inquiry "into the extent and gross causes of the discrepancies occurring between the clinical diagnosis on one hand, and the pathological findings on the other, in 1065 surgical and gynecological cases that passed through the free wards of the Philippine General Hospital and went to autopsy during the first twelve years of its existence."

Leaving out of consideration certain conditions, the analysis of the records shows 3708 diagnoses for 1065 patients. Errors of commission (as determined by autopsy) occurred 729 times (19.6%), of which 287 or 7.7% are recorded as excusable errors. Errors of omission were 1719 or 46.3%, of which 761 or 20.5% were classed as excusable after autopsy studies. Clinical diagnoses were correct 1260 times or in 33.9%, of all the 3708 diagnoses.

A hospital like the Philippine General Hospital, where the faculty of a medical school is ex officio the staff of the hospital; where the well known Bureau of Science and the city morgue are all located upon the same campus, and where each and every clinical diagnoses found in every patient is entered upon the clinical record; where the anatomic diagnosis is made equally complete and where autopsy is secured for well over 90% of patients, offers particularly favorable opportunities for studies of this character.

It is worth noting that Reyes' findings are—as they should be—a comparison between *diagnoses* independent of the number of patients. His 1065 patients had 3708 clinical diagnoses and he did not consider many others that were of little consequence or could not be checked up by autopsy.

The showing made by the study compares favorably with somewhat similar reports elsewhere. There is some consolation in the figures and much that should stimulate clinicians to devote more serious and thorough study to their patients; and there is a sharp warning for all of us who may tend to grow careless under conditions where carelessness is paid for with health or even life.

DON'T FORGET

The Lane Medical Lectures, so fully described in the September issue of CALIFORNIA AND WESTERN MEDICINE, page 1179, are to be held in Lane Hall, Monday to Friday, November 9 to 13, 1925.

Graduate instruction in medicine seems to be the order of the day, and it is difficult to conceive how more valuable or lasting benefit may be secured by any physician in any way interested in the problems of orthopedic surgery than by attending these lectures.

Tom Sawyer on Vaccination—"I ain't denying that a thing's a lesson if it's a thing that can happen twice just the same way. There's a lot of such things, and they educate a person, that's what Uncle Abner always said; but there's forty million lots of the other kind—the kind that don't happen the same way twice—and they ain't no real use, they ain't no more instructive than the smallpox. When you've got it, it ain't no good to find out you ought to have been vaccinated, and it ain't no good to get vaccinated afterward, because the smallpox don't come but once."—Tom Sawyer Abroad.

- The MONTH with the EDITOR -

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

We have been asked to accept a financially profitable advertisement from a new proposed *he-goat* farm.

We also recently declined the advertisement of a slaughterhouse offering to supply fresh "glands" at attractive rates.

"By-products" and "end-products" from slaughterhouses seem to be growing more numerous and expensive. Curiously enough, the price of meat does not decline.

"EATING too much is bound to shorten your life," observed the doctor.

"That's right," agreed the farmer. "Pigs would live a good deal longer if they didn't make hogs of themselves."

"IT IS not natural for your public to be objects of charity," writes Doctor Edwin Schisler (Journ. Mo. Med. Assn.). "One of the first laws of nature," continues this author, "is self-preservation and independence, which is taught in your schools, churches, and your actions of every-day life and handed down by your forefathers. Then why try to make dependents by forcing your different charities upon them?"

A June bug married an angleworm;
An accident cut her in two;
They charged the bug with bigamy,
Now what could the poor thing do?

I See by the Papers That—

—"The State Board of Osteopathic Examiners has been advised by the Attorney-General's office that city school boards could not, under the state law, employ osteopaths to examine children in the public schools, the law requiring licensed medical men for that work."

When King Nebuchadnezzar was restricted to a diet of grass his "hairs grew like eagles feathers and his nails like birds' claws"—at least, so says the Bible in the Book of Daniel.

Here's a hint to beauty specialists! Food fad-dists might also examine this "recent literature" with profit.

From Our Correspondents—

—Lemuel P. Adams, M. D. (Oakland)—The surgical "Conversaciones" are fine, and would like to see more of them in future numbers of our magazine.

—Alfred E. Banks, M. D. (San Diego)—Anent the surgical "Conversaciones," a sample of which is contained in the last issue of the Journal, permit me to state that the innovation is of the utmost interest and promise.

By all means continue this method of attack on the many vital questions which may be thus appropriately briefed.

—Roy Oliver Thompson, M. D. (Calexico, California)—The "Conversaciones" published in your latest Journal I think were a complete success. Give us some more of them, please.

—Julius R. Hamilton, M. D. (Hollywood, California)—I wish to thank you for the courtesy extended in the publication of the case report submitted by me, and your kindly comment in "Editor's Note" certainly lends encouragement to one to send in reports on any future cases that might be of sufficient interest for publication.

Please know your courtesy was appreciated.

—Doctor C. O. Sappington (Oakland)—I was very much interested in the article by Doctor Glaser on "The Doctor in Industrial Medicine," which appeared in the July issue. It was very well done, and I wrote a commendatory note to Dr. Glaser about it.

I wish to take this opportunity to congratulate you on the fine piece of work that you have done in bringing the Journal to where it is at the present time as the finest type of state or section medical journal in the United States.

"Happiness defies the laws of mathematics;
To multiply it you have to divide it."

Doctor James M. Patton (Journal A. M. A., August 22, p. 564) gives an illuminating discussion of "Oculists or Optometrists—Which?" that every doctor, particularly in California, ought to read *carefully*.

It seems that California is to become the perennial proving ground for curious things pertaining to health.

Most doctors are not much concerned with a controversy as to whether or not the present incidence of infantile paralysis in California constitutes an epidemic.

But we are all disturbed by official reports of some eight or ten cases a day.

More than five times as much poliomyelitis as for corresponding periods last year should at least be interpreted as a danger signal.

Mose—Does yuh really love me or does yuh jes' think yuh do?

Rose—Yas, indeedy, Honey. Ah really loves yuh; Ah ain't done no thinkin' yet!

Other County Medical Societies, and even the California Medical Association, would serve themselves and their people well by emulating the very praiseworthy work of the Los Angeles County Medical Association's Narcotic Committee.

Their recent report (Bulletin of the Los Angeles County Society) shows wise conduct in a difficult situation. The report is too long to republish here, but of its nine short paragraphs of advice to members we read:

"Think five times before prescribing for addicts."

"Think one hundred times before joining reform movements."

A GOOD WAY to gauge the truth of any man's argument is to ascertain the motive behind it. Many a cause which seems on a high moral plane is resting on a nicely concealed substructure of self-interest.—Ohio Health News.

"What do you make a week?" asked a judge of an Italian organ-grinder.

"Twenty dollars, sare."

"What, \$20 for grinding an organ?"

"No, sare; not for da grind, but for da shut up and go away."

THE DISTURBING INTERVIEW published in the San Francisco Bulletin by Mr. Frederick L. Hoffman, statistician for the Prudential Life Insurance Company of New York, about the alleged excessive prevalence of cancer in San Francisco, and the Challenge written by this editor and published in the same paper the next day, is still bringing reactions in letters and messages from doc-

tors, and even more so, from the public of the whole community.

Of all the letters and messages, only one—and it was written by a doctor—"protested" about the rough handling of Mr. Hoffman, who, this doctor claims, ought to have the "active support of the medical profession in his work."

The recent serious illness of Doctor H. J. Hanzlik explains the absence of his excellent editorials from CALIFORNIA AND WESTERN MEDICINE during the last few months.

Doctor Hanzlik is professor of pharmacology of Stanford University and a member of the Council on Pharmacy and Chemistry of the A. M. A. It is a pleasure to the editor that his splendid monthly editorials on some phase of pharmacology and therapeutics have been missed by our readers. Doctor Hanzlik has now recovered, and we will again hear from him monthly.

From the Medical Press—

—Does roentgen ray modify the course of whooping cough? Faber and Struble of San Francisco (Journal A. M. A., September 12) say not. They supply some rather convincing evidence upon which their conclusions are based.

—Novasurol, ammonium chlorid, and controlled diet provide promising results in the treatment of patients suffering from nephritis and edema, according to Keith, Barrier, and Whelan (Journal A. M. A., September 12).

The gratifying results from the combination indicated was not secured by either of the three agents alone.

—Calmette and his co-workers keep hammering away on "B. C. G." their anti-tuberculosis vaccine (Am. Inst., Pasteur). Calmette is a veteran, daring and resourceful investigator, and let us hope that something practical comes out of his novel and extensive experimentation with the human-like apes in Africa.

The faster you travel the quicker you will reach the end of the road.
Old age and death are your last stations. Why hurry so?

MR. — OF LOS ANGELES was injured in a motor accident. He was examined by a "licensed doctor," whose report of his findings reads:

"Had an X-ray taken at once for which reads Fourth Cervical to Sixth Cervical left roatary Scoliosis (causing the neck to be pulled to the left side), causing dispoena, preception dull and nervousness. Second: Seventh Dorsal to Ninth Dorsal right Scoliosis (causing torpid condition of liver and kidneys, and auto-intoxication absorbing toxine). A contraction of the Lumbosacrael muscles, drawing right hip posterior, creating severe impingement of sciatic nerve. Also left knee injured by jar and causing severe pain of same. Patients sufers intestinal stasis, absorpion of toxines, and in general a fit subject of rest for at least two months after he is put shape at this office."

The physician to whom the patient eventually applied for service thought the above gem would be interesting news. It is. It is more than that. It's a whole arbeit that tells a lot.

"Exhausted Nutritives"—Under this heading the Medical Journal and Record writes editorially: "We, or at least our children, are urged these days to eat various things which we do not want, and might, therefore, on general principles, seem not to need. Bowing to authority, many of us have followed humbly the leadings of the 'nutrition workers' and have taken spinach and carrots and their ilk as a matter of conscience. We make no complaint against this diet (even if we do not like it), provided we really take in the ingredients which are supposed to be contained in the prescribed foods. Now cometh the agricultural scientist and deposeth that spinach is, in many a garden patch, suffering from chlorosis. If the spinach suffers from chlorosis, will not the human who depends on spinach for his daily supply of iron also suffer from chlorosis?"

Medical Economics and Public Health

THIS IS ENCOURAGING
Commonwealth of Massachusetts
Department of Public Health

Preventive Medicine From Your Family Physician

"There are at least three common diseases that can be prevented. Any case of these diseases in your family means that available methods have not been used.

"(1) Smallpox may be prevented through vaccination. Recently smallpox has been widely spread over the country, and in some places it has been of the malignant type.

"(2) Typhoid fever may be prevented through the periodic injection of typhoid vaccine. 'Vacation' typhoid is mounting with the increased crowding of the country.

"(3) All your family can be protected against diphtheria. Your private physician will explain how.

"Diseases of middle life, due to 'wear and tear,' such as Bright's disease, arteriosclerosis, cancer, and diabetes are increasing. These diseases can be combated by corrected habits and early recognition. Periodic health examinations at all ages may save you from these diseases.

"Talk these matters over with your physician."

The Massachusetts Public Health Department "believing that the *private physician* is the ultimate unit in *preventive medicine* as in curative medicine," has prepared the above postcard for wide distribution. Physicians, hospitals, and all other health workers are invited to help distribute the cards.

This is one example of the many that are now being published, which seems to indicate that the practice of personal health by *public* health departments is on the decline. It is true that some boards of health still continue the operation of "health centers" and other contrivances for the private practice of medicine under the guise of public health, but they apparently are less numerous than they were a few years ago.

Some of the best public health departments have never entered the field of personal practice. Others from time to time announce their withdrawal from the field, and still others, like the Massachusetts Public Health Department, are now urging people to *go back to personal health doctors for personal health services, both preventive and curative.*

The Wayne County (Michigan) Medical Society is actively engaged in an effort to induce all of its members to have a physical examination. Preliminary reports indicate probable success.

A DOCTOR DOES NOT SECURE "BUSINESS" in Industrial Medicine by destructive criticism of the law and the methods of its enforcement.

Two of the three fundamental essentials to secure and hold "business" of this character are a complete knowledge of the provisions of the law as interpreted by the Industrial Accident Commission and a constant, prompt carrying out, in every instance of these requirements. The third essential is not included in this discussion.

Mr. W. H. Pillsbury, attorney for the Commission, authoritatively discusses the law in all that it signifies and in its many and far-reaching applications in "California Safety News" of December, 1924, and March and June, 1925. If Mr. Pillsbury would complete the discussion by a chapter thoroughly outlining doctors' and other medical agencies' responsibilities in the carrying out of this law as interpreted by rulings and actions of the Commission, the result would be wholesome.

Health Officers Recently Appointed (State Board of Health Weekly Bulletins)—Mr. J. J. Saunders has been appointed health officer of Covina. It should be noted that East Covina is under the supervision of the Los Angeles County Health Department, but that the city of Covina is not included under county supervision.

Mr. C. E. Wood has been appointed health officer of Oakdale, succeeding Mr. R. L. Acker, deceased.

Neither of the above appointees are licensed to practice medicine and surgery in the state of California.

Dr. Beverly Young has been appointed health officer of the city of Maricopa. He succeeds Dr. D. W. Sooy. Both are licensed to practice medicine and surgery in the state of California, and Doctor Sooy is a member of the California Medical Association.

The city of Brea in Orange County has turned over the administration of its public health affairs to Dr. V. G. Presson, health officer of Orange County. Doctor Presson is licensed (June, 1925) to practice medicine and surgery in California, but is not a member of the California Medical Association. Dr. W. E. Jackson was formerly city health officer of Brea.

Department Stores Add "Health Sections."—Several clippings of advertisements of certain department stores, calling particular attention to their new "Health Section," have been sent to us both by doctors and patients, inviting comment. A San Francisco department store urges its patrons to visit this "Health Section," where a . . . operator will "diagnose the condition of your health." This "operator" uses, according to the advertisement, a "new and highly scientific device" which, "through a series of vibrations, stimulates the activity of the cells and controls vicima, by which health is maintained." Treatments given by this expert are said to have produced "astounding results," etc., etc.

The only comments we care to make upon such bosh is to call attention to the fact that it constitutes a violation of the Medical Practice Act, both in its offers and claims.

"During June of this year there was no smallpox in Cuba. Covering the same period, 356 cases were reported in Ohio, according to Ohio Health News. Cuba is well vaccinated and enforces vaccination; Ohio does not enforce it."

What about California?

"Fifteen insurance companies are now issuing forms of policies on non-medical plan; twenty-two companies are considering and rather favorably inclined; twenty-five are not expected to adopt the practice, and most of these are unfavorable; seventeen are not issuing policies upon the non-medical plan, but are more or less non-committal as to its advisability."

For a more extended discussion of this interesting development, see editorial, Journal Iowa Medical Society, August.

"Concerning Insurance Examinations"—"Dire consequences are foreseen for insurance companies who abandon the fundamental requirement of a medical examination as a requisite for life insurance.

"The trend is toward this policy. Several companies have already made special classes of policies available to applicants without medical examinations. The theory upon which such procedure is based is that the American actuarial tables are of sufficient experience-length as to warrant such a move. . . .

"The problem involved in the scheme to abandon medical examinations as a requisite to insurance, is not alone the prospects of a decline in the number of good risks and increase in the number of bad risks, but also the prospects for increase of 'state medicine.'

"Once the bars are down and insurance companies are inundated with a host of poor risks, with subsequent losses through claim-payments, then the next step would be to correct an already bad condition by endeavoring to administer to the health of bad risks taken, through elaborate nursing, and medical centers.

"Even now, it is understood, some insurance companies are seriously considering nursing and medical services to the policy-holders as a means of reducing mortality rates among their clientele."—Ohio State Medical Journal.

"THE NATION IS OBSESSED," the Cincinnati Enquirer says, "with laws and bureaus which are designed to emasculate the priceless thing that heretofore has been known as individual liberty. There has been and continues to be a trend toward governmental over-

lordship, a trend fomented and encouraged by the ribald red mockery of government which functions from Moscow, and whose propaganda is prattled and preached from every puffing Punchinello of sinister socialism and communist conflagration in this country. This reaction is seen in the multiplication of federal bureaus and proposed amendments to the Federal Constitution, which, with their resultant clouds of agents, sappers, spies, hangers-on, and official meddlers in the citizen's private life and business."

"Several months ago one of the largest and best known life insurance companies of the country made the surprising announcement that thereafter on business examined within two years additional insurance up to \$10,000 would be issued without medical examination. Another company had already set aside one month a year, during which this privilege was available, and others conceded the writing of twenty-year endowment policies up to \$2000 without medical examination, all showing a tendency toward unexamined business."

Medical and Related Book Service—For several issues past CALIFORNIA AND WESTERN MEDICINE has been carrying the card of F. Gertrude Tallman, who has a medical and related books service in the new Medico-Dental building, 480 Post street, San Francisco.

The surface has hardly been scratched in promoting the sale of worthwhile medical and scientific books in California. We are glad to accept advertisements and promote the interests of concerns like that of Miss Tallman that are being conducted upon a high ethical plane and are serving well a need.

It Affords Us Great Pleasure to admit to our advertising pages, beginning with this issue, the *Scripps Metabolic Clinic and Scripps Memorial Hospital*, La Jolla, California. This splendid memorial is one of the fine, new, modern health-service institutions, donated in the right spirit and being operated in the right spirit, to the credit of scientific medicine and the welfare of the public.

Like so many other of the newer institutions, and with the consent of the benefactor, the articles of incorporation were so drafted as to insure in perpetuity that only adequately educated physicians may practice in that institution. In fact, the intelligence and farsightedness employed up to the present in the planning, construction and operation of this hospital deserves imitation.

An Opportunity for Rest and Recuperation is offered by Miss Alice E. Firth, R. N., at her home, Glen Lodge, Whipple Road, in the foothills above Redwood City. Miss Firth is well and favorably known to many of our members in San Francisco and other Bay cities through her work in the past as supervising nurse in one of our large hospitals and through private duty nursing. Her announcement will be found on the back cover of this and other issues of CALIFORNIA AND WESTERN MEDICINE.

Tuberculin—The chemical composition of the active principle and the nature of the tuberculin reaction are discussed by Esmond R. Long and Florence B. Seibert, Chicago (Journal A. M. A.). The active principle of tuberculin is non-dialyzable; is not absorbed by animal charcoal; is destroyed by trypsin; is maximally but incompletely precipitated by acetic acid at pH 4.0, and is completely precipitated by saturation with ammonium sulphate. The product precipitated by ammonium sulphate is of protein nature, and can be separated into three protein fractions: (1) A water-soluble heat coagulable protein; (2) a non-coagulable, alkali soluble protein, and (3) a non-coagulable, water-soluble protein. Of these, the first and third appear to be the most potent. The nature of the highly specific toxic action of this substance on the tissues of a tuberculous animal is not known. Preliminary experiments indicate that the tissues of the sensitized (tuberculous) animal do not act on tuberculin in such manner as to render it toxic for normal animals, nor do they bind the active principle in appreciable quantity, so as to render a tuberculin preparation less toxic for another tuberculous animal.

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
 W. T. McARTHUR, M. D.....President-Elect
 EMMA W. POPE, M. D., San Francisco.....
Secretary and Associate Editor for California

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—At the first monthly meeting after vacation, held August 17, the following program, as arranged by T. C. McCleave, was presented:

The Epidemiology and Public Health Aspects of Poliomyelitis—Karl Meyer, University of California (by invitation).

The Diagnosis and Treatment of Poliomyelitis—H. H. Hitchcock, Oakland. Discussion of these papers was opened by Harry Foster and Philip Potter, Oakland; W. P. Shepherd, Berkeley.

The Certified Milk Commission and Its Work (illustrated by lantern slides)—T. C. McCleave, Oakland.

The papers on poliomyelitis were presented by special request of the health officers of Oakland and Berkeley, in view of the prevalence of the disease at that time.

Dr. K. F. Meyer, in discussing the public health aspect of acute anterior poliomyelitis, recalled that the infectious nature of poliomyelitis became evident from the clinical and epidemiological observations of Wickman (1905-06) in Sweden, and the transmission experiments of Landsteiner and Popper in Austria, and Flexner and Lewis in this country. On account of the parallelisms of the human and experimental disease both in their clinical and pathological aspects, it was pointed out that inferences drawn from experiments with monkeys may be accepted with a certain degree of safety as valuable to the solution of problems in connection with human cases.

Inoculations of material obtained at autopsy from a human case demonstrated the virus in the brain and cord, basal ganglia, cervical and lumbar enlargements, the sympathetic ganglia, nasal and pharyngeal mucosa, tonsils, and lymph nodes. The virus is not found in the cerebrospinal fluid, blood or viscera. Nasal washings of clinical cases contain the virus during the acute stage of poliomyelitis. It is very much diminished after the first week.

The natural mode of infection is probably by the nasal route. It appears that the virus is propagated in the central nervous tissue of the host, is transferred by chance either directly or indirectly from nasal mucosa of the susceptible to the new host. It is probable that the virus goes directly through the nasal mucosa to the olfactory lobes by means of the perineural lymph spaces, and not first into the circulation and then into the meninges.

A favorite explanation of the epidemiology of the disease is to regard it as a very communicable disease like measles, and much more widespread in the community than indicated by the paralytic cases. Most cases are mild, escape notice and leave protection. In accordance with this theory, only the occasional severe case with paralysis comes to clinical diagnosis. In accordance with this view, one is dealing with a very common infection, always present in the community, but which in recent years has gained an increased virulence.

The virus having been transferred to the nasal mucosa of the second human being, may lodge there, remain active, or may be destroyed. That the latter may happen is shown by the experiments of Flexner and Amoss on the neutralization of the virus by nasal washings. The definite seasonal distribution of poliomyelitis suggests that the recovered case or carrier act as the inter-epidemic reservoir of the virus. All things considered, it seems that the virus has greater chance of surviving in the nasal secretions of the carrier than the recovered case.

Field observations indicate that only slight contact between the carrier of the virus (case, healthy carrier, or person in the incubation period) and the susceptible person suffices for the transfer of the virus. In recovered cases the virus probably disappears, except in rare in-

stances, within ten days to two weeks after the acute attack. The stage of communicability then is from one to two weeks after the onset. This presents difficulties from the standpoint of prevention. The use of convalescent human serum as a prophylactic measure is impractical. Vaccination with altered or changed virus has been tried experimentally, without success. The only method of prevention is isolation until the age of relative non-susceptibility arrives. The patient and intimate contacts are quarantined for three weeks. A search must be made for all persons, especially children, who have been associated with the patient for the previous week. Since the children may be in the incubation period, they are voluntarily quarantined for two weeks.

H. H. Hitchcock, discussing the diagnosis and treatment of acute anterior poliomyelitis, pointed out that this disease is a generalized infection, not confined to children, but seen in all ages. The type of child most often taken in the Long Island epidemic in 1916 was the round-faced child with the central incisors spaced, adults of unusual types as acromegals, hypopituitary, etc., were common.

There are four types seen—the “abortive,” the “dromedary,” the “straggling,” and the “sudden onset group.”

The early symptoms of the disease are the same as seen in any acute infectious disease of childhood. The eyes, however, often present a puffiness of the circumorbital tissue and a glazed porcelain quality in the sclera and cornea.

The “spine sign” (pain and discomfort from flexing the neck or spine) is of importance.

The blood shows 15,000 to 25,000 white blood cells. The spinal fluid is increased in volume, the cell count ranges from 10 to 2500 per cmm., but is rarely opalescent or turbid.

The two most important things in the treatment of the acute phase is the avoidance of meddlesome therapeutics and the prevention of deformities due to muscle-stretching or muscle contractions.

Children should not be permitted to walk until their abdominal and other muscles are strong enough to function normally or are properly protected from stretching and fatigue. Some children are best treated by reclining in bed for a full year. No electricity or massage should be given while there is muscle soreness.

T. C. McCleave, speaking on the work of the Certified Milk Commission, discussed the history of certified milk movement, the organization of a commission by a county medical society, the methods and standards for the production of certified milk, and the medical veterinarian, sanitary, bacteriological and chemical control of the operation of a certified dairy. He pointed out the relative value of certified milk and such other grades of market milk, as guaranteed, pasteurized, etc. The paper was illustrated by lantern slides, depicting unsanitary dairy conditions such as formerly prevailed very generally—and still do to some extent—and contrasted these with slides, showing the methods of production of milk in modern sanitary dairies, with particular reference to certified dairies.

The program was a most instructive one, and brought out a big attendance, many remaining and continuing the discussion in the refreshment hall until midnight.

❧

FRESNO COUNTY

Fresno County Medical Society (reported by John Montgomery, M.D., secretary)—The new out-patient clinic of the Fresno County General Hospital is about completed and will be in use within the month. The Board of Governors of the medical society have expressed themselves in favor of handling all free clinic work in this clinic, and with this in view have sent the following resolution to the Community Chest and to the small clinics operating in Fresno, partly under the support of Community Chest funds:

Whereas, There is no doubt that a certain amount of free clinical work is needed in Fresno; and

Whereas, The Fresno County General Hospital will soon be in a position to handle this work in a completely equipped building, designed for this purpose; and

Whereas, This Clinic will have connected with it, the following:

1. A department of social service, to investigate each applicant, consisting of a social worker and an assistant.

2. A pathologist and complete laboratory organization.
3. Radiographer.
4. Pharmacist.

And in addition there will be available the supervision of the resident surgeon, and the services of an intern, and complete nursing service.

And whereas there will also be the advantage of direct connection with the hospital for patients needing to be referred for hospital care, it is the sense and opinion of the Board of Governors of the Fresno County Medical Society that the clinics conducted by the Fresno County General Hospital will adequately cover the entire field of free clinic work.

It is further the conviction of the Fresno County Medical Society, as represented by the board of governors, that no organization supported by voluntary contributions in Fresno, or by the Community Chest, can afford to put in the necessary expensive equipment, such as x-ray and laboratory equipment and organization, and without these scientific medicine cannot be practiced.

Further, it is our conviction that a clinic which undertakes to operate without these departments is doing an injustice to patients by keeping them away from a place where adequate treatment and facilities are provided. And that the work done in an improperly equipped clinic has a tendency to lower the standards of medicine in this community.

It is further our opinion that the numerous small clinics, which are improperly equipped, make no effort to investigate thoroughly the financial condition of patients, owing to their inability to employ trained social workers for this purpose. And that, therefore, these clinics are imposed upon and people often pauperized.

It is also our opinion that the most efficient work comes through centralization. Therefore, the more this work is divided, the less efficient it will be, and the more difficult to control.

It is also our belief that such smaller clinics are often dominated by "laymen" who cannot grasp the medical point of view. And that the money, which is trust money, being donated by the people to support such clinics, will accomplish more good if spent along other lines, leaving the medical care of the sick and poor to the county, where the law places it.

The secretary of the society is hereby instructed to deliver a copy of this resolution to the directors of the Community Chest. And ask the publicity committee of the society to give this resolution such publicity as seems best.

~

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—A meeting of the Marin County Medical Society on August 20 was held at W. F. Jones' office in San Rafael. The following members were present: H. O. Hund, W. F. Jones, L. L. Stanley, C. De Lancey, Charles B. Marston, J. H. Kuser, and A. H. Mays. This being a business meeting, no papers were read.

On motion of L. L. Stanley, Dr. O. A. Sharpe of San Francisco was invited to read a paper before the society at its next meeting on September 24, the meeting to be held at the San Rafael Club.

The application of Frank Cannon of Point Reyes station was presented by transfer from Idaho, and, on motion duly made and seconded, Doctor Cannon was elected a member of the society. Several communications were read and filed.

~

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert S. Thomas, secretary)—The September meeting will be too late to report in this issue. In addition to the applications from Moser, Reynolds and Schluter, as previously reported, we have three more applications on our files. These come from Charles Israel Titus, now settled in Sacramento, coming to us after five years' practice at Minot, South Dakota, and fourteen years' practice at Great Falls, Montana. He was president of his local society, the Cascade Medical Society; Norris Jones, present resident at the Sutter Hospital; Angus McKinnon, holding a hospital residency at Mater Misericordiae.

Albert K. Dunlap surprised his many friends by the announcement of his marriage to Ruth Yarbrough.

Bert T. Rulison tells of a very enjoyable trip through the East. He spent most of his time at the Mayo Clinic.

The beautiful statue, Maternity, presented by June Harris to W. A. Beattie, now occupies a prominent place at the entrance of Sutter Hospital. The statue has been re-presented to Sutter Hospital as its permanent property.

William Ellery Briggs has returned from his world tour. He took a full year in his travels, a goodly portion of the time being spent in the Orient.

George N. Drysdale, chief of staff at Mater Misericordiae Hospital, has spent one month in the East in the interest of his hospital. He is studying methods of hospital administration. His daughter, Miss Dorothy, chief surgical nurse of Mater Misericordiae Hospital, accompanied him. She is also studying operating-room routine.

~

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Dr. Robert Pollock)—On August 25 the voters of San Diego authorized, through the polls, a substantial bond issue for further development and extension of the service of the San Diego County General Hospital. The intelligent expenditure of this issue will greatly facilitate the medical service for the poor.

The County Medical Society resumed its scientific work, following a dinner at the San Diego Hotel on Tuesday, September 8. The program consisted of three numbers: (1) An excellent case report of unusual interest compiled by A. E. Banks, and in his absence read by Frank Carter, describing a case of osteo-arthritis of Marie coming to autopsy, which showed, as the sole pathology, carcinoma of lung and cerebrum. This paper was discussed at some length by Drs. Redelings and Carter. (2) Ben F. Eager presented a patient on whom he had recently made a division of the posterior root of the right Gasserian ganglion for the relief of painful trifacial neuralgia of ten years' standing. This case, from the standpoint of prompt relief, freedom from disfigurement and quick release from hospital and return to work, left little to be desired in the handling of this stubborn condition. (3) James F. Churchill gave an extremely interesting—because clear and informal—exposition of electro-cardiography. Churchill made very clear the many ways in which the electro-cardiogram is a distinct aid to the clinical study of heart conditions, taking pains to show just what the instrument can do and what are its limitations. He supplemented this talk with a presentation on the screen of graphic records of many of the abnormalities which the instrument can portray. This paper met with an enthusiastic reception, and was discussed at some length by Owens and White of the Naval Hospital. At the close of the discussion on his paper, Churchill took occasion to thank the commandant and officers of the Naval Hospital for many courtesies received at their hands, and to express in high terms of commendation the excellent scientific work, both clinical and research, which is being carried on by the splendid staff of this hospital.

The program committee announced the October meetings to be featured by a trip to El Centro, where the sister societies of San Diego and Imperial Counties will discuss jointly a program based on casualty surgery.

~

SAN FRANCISCO COUNTY

St. Lukes Hospital submits an interesting report for the month of August. They had a daily average of 150.9 patients, with 4527 patient days. Of these, 106 days were free and 308 days were utilized by patients who could pay only a part of the cost of their care. Thirty-six thousand seven hundred and thirty-four meals were served at a cost, exclusive of prorated overhead and general expense, of 21 cents a meal. Eighty patients were refused service in the free clinics, and were instructed to consult their private physicians. One thousand four hundred and fifty-one persons requested reduced rates.

This hospital issues a remarkably concise and well-prepared monthly report of its doings.

St. Joseph's Hospital Staff Considers Construction Problems—On September 2 R. G. Brodrick of Oakland

spoke before St. Joseph's Hospital staff of San Francisco on "Latest in Hospital Construction," A. S. Musante presiding. The following is an abstract of the address:

"The problem of constructing a modern hospital presupposes a consideration of a proper site and here, also, the old buildings. Elastic plans to meet the growing use of hospitals and the control of an entire city block are best. The ideal should be aimed at. Economy is often questionable, especially if based on cost per bed or square feet. Cubic cost is better. Two thousand five hundred cubic feet is the legal requirement, but 7500 cubic feet is required; figuring the school of nursing, 10,000 cubic feet is needed per patient. Maintenance costs must be considered. The culinary department can cost one-third or one-half of it, and labor now makes up 50 per cent. Much depends upon types of patients—pay, part-pay, and free. Latter should be limited, so those straining to pay low rates will be able.

Tendency in rooms is to make them attractive and free from somber aspects and odors. Color is needed for the interior. All conveniences must be considered. The size is smaller than before, 11x11 being used. The bed is placed out of the draughts, between the door and window. Patients' call system is by flash, not bell. The double-hung sash is still the best window, the top transom being omitted. Telephone and radio are now used. Facilities for hospital and visiting nurses are needed. Great numbers of baths and suites are not profitable, about one bath to fifteen patients being the average. Wards are smaller than ever, eight beds being the maximum. Utilities are placed in middle.

The surgery is placed where there is no passage to anything else, to eliminate visitors and be able to close it off. Compact rooms, with much of the equipment built in and about 16x18x20, are used. Viewing platforms, reached from hall, are used. The windows are getting smaller and artificial light is used more, as it is steady. Spotlights are not favored for general lighting, but are used to illuminate deep fields. Nitrous oxide is piped into the surgery from large tanks. Compressed air, alternating and direct currents and x-ray connections are provided. Floor drain and other plumbing are not used, but the anteroom can house them. Distilled water is being replaced by sterile water. Scrub-up room should be next to surgery. Sterilizing outfits are placed between operating rooms, and pressure types are best. All the piping can be built in stalks, easily accessible. Light green tiling is better. Surgical laboratories are placed near surgery, but general ones should be nearer internists' floors and out-patient department. The x-ray room should be convenient to operating room, on account of its growing importance to urological and other procedures.

Metabolic, electro-cardiographic, post mortem, and animal experimentation rooms should be convenient to laboratory. Handle dead so as not to be seen by patients. In admitting patients, ambulance patients must be kept separated from those afoot. Provide for observation and isolation of cases.

The culinary department must provide proper place, construction, and equipment for the kitchen. Trays are distributed by elevators. The dish-washing room should be deadened to limit the noise. Door-closers, ball-bearing butts, hardware for doors, laundry, signal systems, and physiotherapy need study, the latter being desired by the public, but should be in charge of a technician and be supported by the staff. An emergency service is needed in large cities for traffic and other wounds.

On October 14 Dr. Harry Spiro will speak on "Modern Diagnosis and Treatment of Heart Disease," and Dr. Earnst Gehrels on "Gastric Surgery."

SISKIYOU COUNTY

Siskiyou County Medical Society (reported by Cordes W. Ankele, secretary)—The members of the Siskiyou County Medical Society met, with their wives, at luncheon on August 30 at Crag View, Castella. Following the luncheon a business meeting was held out under the trees, while the wives were engaged at cards. There was a general discussion as to the effect of the newly adopted fee schedule, followed by a discussion on the treatment of chronic urinary infections.

H. A. Morse of Hilt was elected to membership. The

following members were present: R. H. Heaney, Charles Pius, Szabo Kalman, W. E. Tebbe, C. W. Nutting, and C. W. Ankele.

CHANGES IN MEMBERSHIP

New Members—Lawrence J. Bernard, George Eric Chapman, J. Paul de River, Thomas E. Gibson, Robert M. Laddon, A. A. Maximova-Kulaev, Edmund J. Morrissey, Harry J. Pruett, Sergius S. Rakitin, Guy Schoonmaker, San Francisco; Frank M. Cannon, Point Reyes Station; C. Dana Carter, Clarence D. Dickey Jr., Roscoe A. Ford, Alessandro Jardini, Roscoe M. Nicholson, A. W. Williams, Los Angeles; Luella S. Cleveland, San Jose; Glenn G. English, Hollywood; Bernard H. Gilbert, Montague; Charles C. Hall, Oda T. Leftwich, Rufus I. Newell, Oakland; Burton A. Myers, Hammonton; William G. Tucker, Dunsmuir.

Resigned—John E. Nast, San Francisco.

Transferred—Adolph Kutzmann, from San Francisco County to Los Angeles County; Charles E. Mordoff, from Fresno County to Alameda County; Harper Peddicord, from Mendocino County to San Mateo County.

Deaths—Skeel, Roland Edward. Died at Los Angeles September 4, 1925, age 56. Graduate of the University of Michigan Medical School, Ann Arbor, 1890. Licensed in California in 1919. Doctor Skeel was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

EXTENSION LECTURE SERVICE

In the September issue of CALIFORNIA AND WESTERN MEDICINE was extended an invitation to the members of the California Medical Association to join the Extension Service. The revised list, as here published, will be issued as a reprint on November 1 for the use of county secretaries. Further names of members who desire to join this service, together with the titles they are prepared to present, will be added to this reprint if furnished the state office before October 20.

Harry E. Alderson, M. D., 320 Medico-Dental Building, 490 Post Street, San Francisco.

1. A Skin and Syphilis Clinic will be Held of Locally Selected Cases (five or six).
2. Newer Methods of Therapy in Dermatology.
3. Therapy of Lues.

Walter C. Alvarez, M. D., 803 Liebes Building, 177 Post Street, San Francisco.

1. The Taking of a Gastro-Intestinal History and What It Means When You Get It.
2. Practical Points in the Diagnosis of Gastro-Intestinal Disease. (Lantern slides.)
3. New Light on the Cause and Significance of High Blood Pressure. (Lantern slides.)

Utah State Medical Association

T. C. GIBSON, M. D., Salt Lake City.....President
W. R. CALDERWOOD, M. D.....President-Elect
FRANK B. STEELE, M. D., Salt Lake.....Secretary

The complete transactions of the Annual Session, held September 7 to 12, at Salt Lake, will be published in November, as the very splendid transcript of the proceedings was not received in time for this issue.

A NEW YEAR

So far as the Utah State Association is concerned, we begin now a new year. President Gibson has not as yet appointed an editor for CALIFORNIA AND WESTERN MEDICINE to take the incumbent's place. But we still, as editor, want at this time to bespeak for him, whoever he may be, a hearty co-operation from the several county societies.

The Utah section of CALIFORNIA AND WESTERN MEDICINE is meant to be representative of the state. The only way in which any editor can gather the local news of interest is through the co-operation of the several secretaries, each of them sending him a monthly report. And if they will do this, if they will take this little trouble, if they will give him the chance to give their section representation—then we can build up the Utah section to a point where Doctor Musgrave, editor of CALIFORNIA AND WESTERN MEDICINE, will have to give us more space—to where he will be glad to do it. He has already said he would be glad. So, now, all together for the new year. Let's make him show that he meant it—every word. Send in your news notes after every meeting. You're each and every one entitled to a part of Utah's space. Will you use it or won't you? Come on. Let's go for the next twelve months.

HE WHO RUNS

As this is written, the meeting of the State Association is drawing to a successful close, with a good attendance, over 190 men having been enrolled among the visitors from two neighboring states. An election has been held, and Doctor T. C. Gibson has been installed president for the year to come, Doctor Calderwood has been named as president-elect, and Doctor Frank Steele has taken up the secretarial duties laid down by Doctor William Rich. Under the guidance, and assisted by the service of such men, the association can hardly do more than look upon the future with confidence.

As for the convention itself, consisting as it did of the routine conventional activities combined with and followed by the post-graduate program so ably furnished by the committee in charge, one can say little save that it was a gratifying success both for those who gained much or little from it. For a man may profit from such a course of instruction in two ways: Should he be deficient in knowledge on the subjects covered, then he may learn and strengthen himself. Should he already be possessed of the knowledge advanced for his apprehension, then is he strengthened and supported in his application of it by the knowledge that the men from far places—those who have had a wider experience than him—

self—have, as it were, placed the cachet of approval upon his methods and technic. There is only one trouble with such gettings together as the last convention, and that is: they come not often enough. He who runs may read.

There is something compellingly beautiful in that old-time oath with its pledge of clean, unselfish, sincere, unfaltering service. And there is something beautiful in the work, the face, the very soul of the man who lives up to it. There is something almost divinely beautiful in the life of the man—the doctor, the physician, the healer, the comforter, as he walks his daily path. He is a disciple of Hippocrates, who gathers to himself the intangible yet priceless values of the look in the eyes of a woman who has gone down into the valley of the Great Adventure of giving life and found him there a strong arm to lean upon rather than a broken reed; who earns for himself the clasp of baby arms, the touch of baby lips, in payment for the help he has rendered in a time of pain and danger, or reaps the harvest of the tears of thankfulness in parents' eyes. Disciple of Hippocrates—he serves his race, himself, and his God.

But what of the hypocrites? What of the man who, forgetting the oath he swore to follow, prostitutes his pledge and himself and his craft? You and I meet him and his work from day to day, and sometimes we rave, and sometimes we curse, and sometimes we simply weep. He it is that brings the blush of shame to the true doctor. We mean the man who deliberately advises an operation in order to gain a few dollars on the basis that, "if the patient survives it is all right." We mean the man who deliberately, under the guise of a "D. C."—that phraseology which, like the mantle of charity, covers a vast number of sins—deliberately for a price destroys incipient life, and "gets away with it." We mean the man who, in order to aggrandize his assumed reputation or his pocketbook or both, plants the barb of unkind criticism in the mind of a patient of some other member of his profession in order to gather that patient to himself. Surely, surely, the true disciple of Hippocrates will criticize only when criticism is deserved. Wherefore, we mean, of course, those men in an age when ignorance can no longer be held an excuse, who so conduct their service to their patients that such criticism can honestly be brought against them by sincere and informed members of their craft.

What we mean—if you get what we mean, and we hope to God you do—is simply this: Let's be disciples of Hippocrates; let's be true to that grand, uplifting, exalting oath, and let's NOT be hypocrites.

I'm a doctor. I hope I'm a good one. I try to be, at least. Anyway, I'm proud of my profession and its accomplishments. And I hope and I pray in my innermost soul that the day may come when the true physicians, of which there are such a glorious number, will stand shoulder to shoulder for the good of the race and the profession, and he who will not subscribe to the higher ideals of our calling shall more and more, like Lucifer, the Archangel who rebelled against the Most High—the hypocrite, wearing his cloak as a disguise rather than a glory—be driven out, uncloaked, unveiled, shown in his true colors, for the racial parasite he really is.

HIPPOCRATES OR HYPOCRITES

We don't know. We never met him. But if the code which bears his name is any criterion to go by we feel that Hippocrates must have been a pretty good old guy, with a large measure of optimism and more than the average of altruism in his makeup—both of which qualities could be more assiduously cultivated by the medical profession of today.

Anyway, the Hippocratic oath is a thing to remember as something more than a mere step in the program of being endowed with the degree of M. D. And as we sit up in a tree and watch the show go by we sometimes wonder just how many of the men who have taken that oath before that degree was conferred *do remember* it—at least in the sense they should.

Into the Hippocratic oath was written a code which, if followed, would make of the doctor a man and a minister to his fellows in nowise short of a priest. One who follows it as it was meant to be followed must be, as a result of its mere following, a man set aside from his fellows, for purity of thought and action—a man of men—one to be looked up to, trusted, given every confidence.

And is not this the ideal of the profession aside from the daily battle of the disease just as much as it was in the days of the ancient Greek? The men who have gone down in history, whose names will live as benefactors of the race, are the men who *have served*. Service is the measure of the true man's worth—be that service rendered to a state, a nation, or a little child.

And so, it would be even more advantageous if one could have the opportunity to read a little more—a little oftener—those things which can refresh his recollection, build up his information, give him a renewed confidence.

Convention Notes—The ubiquitous detail man was on the job. A medical convention without a few detail men is like a circus without peanuts and pink lemonade.

We think more men should have attended the lectures on blood chemistry, serology, bacteriology and kindred subjects. Too many doctors seem to think that the difference between a gram negative and a gram positive organism is similar to a parliamentary vote. As a matter of fact, whether the negatives or the positives have it the patient has it in either event.

Doctors who come to a convention for the purpose of renewing personal acquaintances or airing their own viewpoints should be given a private lecture room for the purpose. Some of the men want to hear what the lecturer has to say while he talks.

We wish to disabuse the idea that the chairman of the banquet committee was under the table. In reality he was professionally engaged with a patient who could not retain her food (not at the banquet).

The thanks of the Association should go to the University of Utah for the use of their buildings during the convention and the co-operation of the medical faculty during the convention week.

Cecil Alter, in charge of the Weather Bureau, should also draw a vote of thanks. The brand of weather which he distilled during the convention could have been equaled only in California, where, rain or shine, the sun shines 100 per cent. Well, after all, Utah is best described in the words of the French artist who visited one of her canyons and sought to describe it. Having used up all his superlatives, he ran out of words and finally summed it up as "Pretty darned good." It is.

A noticeable factor in the convention was that the lec-

turers talked horse sense. It's a good thing to mix with every prescription or each bit of professional advice.

Anyway the convention was a success.

Utah Notes (reported by J. U. Giesy, associate editor)—Meeting of Catholic Association—Welcomed by Governor George H. Dern and the Rt. Rev. Joseph S. Glass, C. M., D. D., bishop of the Catholic diocese of Salt Lake, the members of the Mountain States Conference of the Catholic Hospital Association convened for a two-day session Wednesday morning at the Holy Cross Hospital at 8 o'clock, where Holy Mass was said by Bishop Glass followed by his opening remarks, which welcomed the visitors to the city and to the hospital. Governor Dern added his greetings and welcome to the visitors, followed by a greeting from Dr. J. J. Galligan.

An attractive program of scientific discussion by visitors and local hospital workers, interspersed with social features, continued during the two days' session.

Nevada State Medical Association

A. J. HOOD, M. D., Elko.....President
HORACE J. BROWN, M. D., Reno.....
.....Secretary and Associate Editor for Nevada

PROCEEDINGS OF THE TWENTY-SECOND ANNUAL SESSION, ELKO, NEVADA, SEPTEMBER 4, 5, 6, 1925.

The twenty-second annual meeting of the Nevada State Medical Association was called to order by President W. M. Edwards at 10 a. m. in the courthouse at Elko, September 4, 1925.

The program was rendered as follows, with excellent presentation of timely subjects and splendid attention:

Professor Peter Frandsen, Reno, representing the American Association for Medical Progress—"Anti-Scientific Propaganda." He gave history and aims of the American Association for Medical Progress, and answered questions often asked. This association is safeguarding the public against anti-scientific methods. He recommended public health meetings for the public, and explaining to patients the principles of therapy and the prevention of disease. Discussion by Henry Albert, T. W. Huntington, E. L. Gilcreest, Peter Frandsen.

Henry Albert, M. D., Reno—"The Prevention and Control of Infantile Paralysis." As outbreaks have occurred this year, Nevada may expect an epidemic this fall or winter. Expression of anxiety and resistance, dull sclera with resistance to flexion of neck and a slight Kernig's sign are of definite diagnostic aid. Tapping of spinal canal relieves pressure, and is of therapeutic value. Isolate nurse and family with patient. After three weeks, with proper antiseptic precautions, family may leave premises. Circular used at Fallon. Discussion by H. W. Sawyer, W. L. Samuels, H. J. Reese, W. H. Hood.

Arthur Collis Gibson, M. D., San Francisco—"Chronic Paranasitis," with slides. Discussion by Henry Albert, William Edwards, Anna De Chene.

Edgar L. Gilcreest, M. D., San Francisco—"The Treatment of Fractures of the Elbow Joint and the Lower End of the Humerus," with slides. Discussion by A. J. Hood, R. A. Bowdle, A. R. Kilgore, J. F. Kerby, T. W. Huntington.

J. F. Kerby, M. D., Salt Lake City, Utah—"Anomalies, Diseases and Injuries of the Spine," with slides. Discussion by H. J. Brown, R. A. Bowdle, E. L. Gilcreest, H. Zimmerman, C. E. Piersall, H. Albert, Albert Soiland.

Eric A. Larson, M. D., Woodland, California—"The Treatment of Peptic Ulcer." Discussion by A. R. Kilgore, E. L. Gilcreest, Albert Soiland, William Edwards.

The Reno Radium-X-ray Association presented a four-reel movie on "Pulmonary Tuberculosis" at the theater.

September 5, 1925, 9 a. m.—The business meeting was called to order by President Edwards.

It was moved by D. A. Turner that the reading of the minutes be omitted. Seconded by W. A. Shaw. Carried.

The secretary's report was read, and it was moved by Turner that the report be approved and that the secretary be allowed to buy a filing cabinet, which is now necessary. Carried.

The report of the delegate to the American Medical Association was read.

The report of the Judicial Committee was read by H. J. Brown. A telegram from Dr. Eby was read by the secretary, and a motion by H. J. Brown was made that we give Dr. Eby our sympathy in his illness, and regrets that he could not attend this meeting.

Dr. Turner asked that the doctors of Nevada enter the United States Medical Officers Reserve Corps.

Election of Officers—W. A. Shaw nominated W. L. Samuels for president. R. Bowdle nominated A. J. Hood of Elko for president. H. I. Brown moved that the nomination be closed and the votes be made by written ballot. Turner seconded the motion. Carried. A. J. Hood received seven votes and W. L. Samuels received two votes. It was moved by Olmsted and seconded by Roantree that the secretary cast a unanimous ballot for Dr. Samuels as vice-president. Carried. It was moved by Roantree that C. W. West be nominated for second vice-president, and that the secretary cast a unanimous ballot for him. Carried.

C. E. Piersall nominated V. A. Muller for secretary and treasurer. W. A. Shaw nominated H. J. Brown. Dr. Brown received nine votes, and Dr. Muller received four votes.

H. J. Brown nominated W. A. Shaw for re-election for a three-year trustee. Secor moved that the motion be closed, and the secretary cast a unanimous ballot for Dr. Shaw. Seconded by Dr. Bowdle. Carried.

H. J. Brown moved that all physicians who are our guests be honorary members. Seconded by Shaw. Carried.

H. J. Brown also moved that the Nevada State Medical Association pay all that it is able to pay of the expenses incurred by the Elko County Medical Society for the 1925 meeting, and that we express a vote of thanks to Elko County for their splendid entertainment. Seconded by Dr. Bowdle. Carried.

A motion was made by Dr. John E. Worden to have the 1926 meeting at Reno. A motion was made by R. A. Bowdle that the next meeting be held at Ely. The vote was a tie. A motion was made by W. L. Samuels, and seconded by Turner, that the 1926 meeting be held at Bowers Mansion. Carried.

The president appointed the following three committees to work with the University of Nevada Agricultural Extension Division: Henry Albert, H. J. Brown, and C. E. Secor.

Saturday, September 5, 1925—Miss Mary Stillwell of the Nevada Agricultural Extension Division of the University of Nevada gave a talk on "Health Contests Among 4-H Clubs," with demonstration by two club girls. Discussion and approval by T. H. Huntington, H. J. Brown.

It was moved by H. J. Reese that the president appoint a committee of three to confer with the University of Nevada to co-operate with yearly assemblages in health problems. Carried.

Albert Soiland, M. D., Los Angeles—"The Granulomata, Hodgkin's Disease, Lympho, Sarcoma, and Leukemia." Discussion by A. R. Kilgore, J. F. Kerby, H. Zimmerman, Eric E. Larson.

Miley B. Wesson, M. D., San Francisco—"Conservation vs. Radical Surgery for Traumatic Rupture of the Kidneys," with slides. Discussion by E. L. Gilcreest, Eric E. Larson, T. H. Huntington, R. P. Roantree, R. A. Bowdle.

Alfred B. Spalding, M. D., San Francisco—"The Surgical Utility of the Pelvic Fascia in Cases of Cystocele, Rectocele and Uterine Prolapse," with slides. Discussion by E. A. Larsen, Miley B. Wesson.

P. K. Brown, M. D., San Francisco—"The Medical and Surgical Treatment of Angina," with illustrations. Discussion by W. W. Washburn, E. L. Gilcreest.

H. J. Brown, M. D., Reno—"The Workings of the American Medical Association." Discussion by John E. Worden, Miley B. Wesson.

W. W. Washburn, M. D., San Francisco—"The Modern Surgical Treatment of Goiter," with slides. Discussion by

E. A. Larsen, E. L. Gilcreest, P. K. Brown, S. M. Sproat, W. L. Samuels, R. P. Roantree.

Banquet at Lamoille.

The following members were in attendance at various times during the meeting:

William M. Edwards, Henry Albert, Anna B. De Chene, R. A. Bowdle, D. A. Smith, W. L. Samuels, John E. Worden, W. A. Shaw, A. R. Kilgore, W. H. Hood, C. E. Secor, A. J. Hood (Elko), A. C. Olmsted, C. W. Eastman, C. E. Piersall, H. J. Brown, J. T. Reese, H. W. Sawyer, R. P. Roantree, D. A. Turner, H. A. Paradis.

The following visitors were also present at various times during the meeting:

T. W. Huntington, M. B. Wesson, J. P. Kerby, J. P. Warren, E. L. Creveling, Peter Frandsen, Edmund White, A. C. Gibson, Eugene Benjamin, E. Eric Larson, H. A. Collings, A. Soiland, Mary E. Stilwell, W. W. Washburn, E. L. Gilcreest, G. J. Hull, A. B. Spalding, R. H. Travers, H. Zimmerman, S. M. Sproat, P. K. Brown.

CORRESPONDENCE

C. O. Sappington, M. D., Oakland, Calif., commenting on the article by Doctor Shuman, "Questionable Diagnostic Methods," published in the August issue of CALIFORNIA AND WESTERN MEDICINE, page 1027, says:

All progressive clinicians will, no doubt, agree with Dr. Shuman that it is not to the best interest of any sick patient to be examined by too many physicians. Refined diagnoses, so called, are frequently made at the expense of comfort and safety.

The standardization of diagnostic procedures is a necessity, which might be handled through standardization committees as have other procedures.

One is inclined to agree with Dr. Fulton's idea that perhaps the greater of two evils in regard to laboratory methods is neglect, rather than abuse. Medicine is certainly more scientific today than ever before. As President Ewer has so well remarked, "Cold science, effective but not always convincing, has come into nursing and medicine as sentiment has been squeezed out." As a clinical guide-post for future use, perhaps Sir James MacKenzie's observation is noteworthy: "The next advances in clinical medicine must be the recognition of the diseased state before it has produced gross structural changes and the recognition of the conditions that predisposed or induced the disease." This surely calls for diagnostic thought.

Dr. Bine commented most interestingly on the "old fogey" physician—as he was called by some of his more modern younger associates—and the experiences during an epidemic in which the older man was more valuable than the younger ones. As a representative of the younger group of medical men, let me say that I heartily wish that there was more genuine respect between the younger and older men. Respect, of course, is a mutual feeling. Many younger men feel that, through newer methods, they know more; many older men feel that, through more experience, they are superior. Both err, for both new ideas, methods, and long experience are essential. In perhaps no other walk of life than the practice of medicine do years of experience play so vital a part. Yet young fellows often set themselves up as specialists when barely out of school, and one hears tales of incomes which overreach five figures within the first year of specialty practice, while most of our good practitioners today know that years of labor and thought are necessary to build up such an income.

Perhaps a bit more of regard for the experience of the older man, on the part of the young fellows, and a little more commendation and encouragement of the young practitioner by those in seniority would improve relations. And, again, perhaps all of us, old and young, should more keenly realize that "life is short, the art long, judgment difficult, delay dangerous, experience fallacious."

Manila, P. I., August 5, 1925.

My dear Dr. Musgrave—Your kind appreciation of the actual status and development of the Department of Legal Medicine in the Philippines, as outlined in your editorial in the August issue of California and Western Medicine, gives me the strongest encouragement to maintain my devotion to the subject, and to work harder for a greater extension of its application to the legal and social needs of this country.

In this connection permit me to inform you that, thanks to the inclusion of the subject of Legal Medicine among the required subjects in the courses of law and medicine, and the relatively more intensive and practical teaching of the same during the last decade, *we are actually noting here a remarkable change of orientation taking place in the procedure of the courts of justice in relation to medico-legal questions and problems.* The prosecuting attorneys, at least in the city of Manila, deal with these questions by making previous careful preparation with the aid of medical experts, thus compelling the side of the defense to adopt equal or better means and thereby affording the judges to have a better basis to understand and decide on scientific matters.—Sixto De Los Angeles, Professor and Head Department of Legal Medicine.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

A case was recently tried before a jury in the Superior Court of this state, involving the following situation:

A practicing dentist had made certain false teeth for a patient and had delivered them to her upon the claimed understanding that she would pay for them within a certain time. Before the teeth were paid for, the patient called on the dentist for additional examination and work, and, as claimed by plaintiff, while she was permitting her mouth to be examined, the dentist forcibly removed the teeth and stated to the patient that when she had paid for the teeth she could have them back, but that he would not return them unless and until he had been paid.

The patient sued for damages, claiming that title to the teeth had passed to her upon the credit of her contract to pay, and that the defendant dentist committed an assault upon her person in forcibly taking the teeth, and that his remedy was purely contractual for the price of the teeth. A jury was demanded by plaintiff and there was evidence that plaintiff suffered from shock as the result of the withdrawal of her teeth, a physician testifying that he gave plaintiff an opiate to quiet her nerves. After argument, the jury awarded plaintiff \$500 damages, an amount very much in excess of the value of the teeth.

On motion for a new trial, the trial judge permitted the verdict in favor of plaintiff to stand, but reduced the amount to \$250, on the ground that the damages awarded were excessive.

"Anybody hurt in the wreck?"

"One gentleman, I believe."

"Bones broken?"

"I think it was his heart. He sat down by a leaking suitcase and shed tears."

"There goes a man who thinks in terms of millions."

"He doesn't look to me like a great financier."

"He isn't; he's a germ expert."

LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

KLIM

**is uniform milk
from which only the water
has been removed**

K LIM is standardized to 3.33% butterfat content when liquid, or 28% when dried.

When KLIM is reliquified, the butterfat, in fine globular division, remains in a perfect emulsion.

A cream line cannot fail frequently to create differences in the fat content of the baby's bottle or the child's ration. In the latter case the cream too often finds its way to the parent's coffee. KLIM eliminates these hazards.

The Psychiatric Clinic in the General Hospital—The development of psychiatric clinics, behavior problems in childhood and adolescence, treatment of neurotic children, and adolescent and older patients are some of the topics discussed by I. J. Sands, New York (Jour. A. M. A.). He asserts that the psychiatric clinic in the general hospital supplies the long-felt want of a readily accessible source of information on general psychiatric subjects for the medical profession at large. The mental clinic in a general hospital is in a position to furnish information on psychiatric subjects that are not encountered in state hospitals. There is a great need for an exhaustive study of endocrine diseases, especially in their histopathologic phases. Likewise, there is a great need for further research in brain pathology. The country at large is at present aroused over the great wave of criminality that is sweeping over it. Everything is being offered as a possible cause of this problem, from the greatest achievement of science to the very elements of nature itself. Impossible laws, bigoted reformers, the automobile, the motion picture, the radio, lack of religious training, and even the very rays of the sun have been enumerated among the possible causes. When one considers that approximately two-thirds of the population of our penal and correctional institutions have been shown by surveys to be suffering from a mental disease or defect that has a definite bearing on their anti-social conduct, it is but logical to expect psychiatrists to produce explanations for and offer solutions of this problem. Recent tragic events have shown the importance of the recognition of the various problems in childhood long before their manifestation in overt acts of anti-social conduct. These have elicited considerable unfavorable editorial comment from the lay press. Recently, psychiatric opinion has been subjected to severe criticism because of the diametrically opposed views which alienists have offered in some of the notorious medico-legal cases, and also because the poor person is frequently deprived of expert psychiatric opinion that is purchased by the rich. The first criticism can be combated by merely calling attention to the fact

(Continued on Page) 1346)

WELLSWORTH MONAXIAL BIFOCALS

The only bifocal ground on a common axis

The elimination of the "jump" or prismatic displacement, which occurs when the eye passes from distance to reading portion, is accomplished by grinding both distance and reading fields with their centers of curvature on the common axis which passes through the junction of the near and distance fields of vision. Line A in the above illustration represents this common axis. This makes these two curves tangent at their junction

tion and permits the passage of the line of sight over this point without a sudden displacement of the image—no blind area or extraneous prism.

This principle of grinding multi-focal lenses is owned and patented by the American Optical Company.

Specify Wellsworth Monaxials on your next Bifocal Rx.

Literature from

E. BILHUBER, Inc.

25 West Broadway, New York, N. Y.

Disturbances of Vision Due to Digitalis—Disturbances of vision resulting from the internal use of digitalis have been known at least from the time of Withering. Such disturbances have only rarely been described in the English literature, but have been carefully reported in German and French. Their occurrence at present in this country is very infrequently recognized. Because of the importance of noting visual disturbances in all grades of digitalis intoxication, H. B. Sprague, P. D. White, and J. F. Kellogg, Boston (Journal A. M. A.), report a series of seven cases. These cases present symptoms of a toxic amblyopia with dimness of vision, flickering and flashing scotomas and marked disturbance of color vision. All these seven patients received an excessive amount of digitalis. In all but one case, this was due to incorrect dosage by the physician in charge, or misunderstanding on the part of the patient. Five patients complained of a defect of color sensation; four had yellow vision, one red-yellow, and two green. All complained of decrease of visual acuity, and three said that they seemed to be looking through mist. Two had difficulty in focusing the eyes or reading, two had definite scotomas, and three had flickering before the eyes. In one instance the patient said that surrounding objects in sunlight appeared covered with snow. In two cases the visual disorders preceded the gastro-intestinal and cardiac effects; in two others, disturbances of the eye were associated with nausea and vomiting as the first toxic symptoms. Two patients with marked visual effects had no change in cardiac rate or rhythm, and one of these had striking xanthopsia without either nausea or cardiac effects. In three cases, extreme muscular weakness, described in digitalis intoxication, was a prominent feature. This, with the gastro-intestinal complaints, was considered by the patients of more serious importance than the eye symptoms; and it was, therefore, necessary to question them carefully to secure an adequate description of their visual disorders.

PSYCHIATRIC CLINIC IN GENERAL HOSPITAL

(Continued from Page 1341)

that difference of psychiatric opinion as compared with difference in legal opinion is like an harmonic symphony compared with a rhapsody of incoherence. The second criticism may ably be combated by the psychiatric clinic in a general hospital, which would be in a position to offer expert advice to the poor. The presence of the psychiatric clinic in the general hospital is assured. The success and failure of any one given clinic will depend on its personnel. The director of the clinic must be a psychiatrist of wide experience and special aptitude for his work. The study of mental disorders requires a long apprenticeship, and there are no short-cuts for acquiring psychiatric knowledge and experience. A six months' course of training in a foreign country in one of the many modern schools of psychology or psychopathology is surely inadequate to enable a man to assure leadership of such a clinic. A properly trained psychiatric social service worker is likewise indispensable for the success of the clinic. A properly trained psychologist is a very desirable addition to the personnel. Properly kept records and proper clerical assistance will enhance the value of the clinic.

"Milk is recommended as a sure source of vitamins and minerals. Are we certain that these are present in the milk we happen to purchase? They may be all there, but it is known that their quantity varies according to the food of the cow, and, in the efforts to secure a maximum of lacteal fluid, the proportion of food materials in the milk is anything but that of the cow on her natural pasturage. It looks as if we might come to a time when we would need to prescribe for the child, not merely milk which we know to be comparatively free from bacteria and containing relatively right amounts of proteids, sugar and fat, but also milk that fills the specification that there be sufficient representation of the accessory food materials and of minerals."—Editorial, Medical Journal and Record.

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA
THE IMPROVED
ALKALINE WATER

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Diseases of the Rectum and Pelvic Colon. By Martin L. Bodkin. 2nd ed. 487 pp. Illustrated. Review copy supplied by the publishers, E. B. Treat & Company. After Pennington's great work on diseases of the rectum and colon, Bodkin's book comes in the nature of an anti-climax. It is not up to date, it is not sufficiently revised. For instance, instead of the emetin treatment hypodermically, the now long antiquated ipecac pill treatment is given for amebic dysentery. In mixed piles, the clamp and cautery is advised for the skin portion of the pile. No mention is made of quinine and urea as the drug of choice for the injection treatment of piles, a method now widely practiced. Alcohol, as a remedy for pruritus ani, is not mentioned by the author.

In the chapters on surgical treatment of malignant growths, entire pages are quoted from Tuttle and Munimery. And what are the dates of publication of these pages? Why 1907 and 1912. No! Bodkin's book is not up to date, but it may be enlarged.

Diseases of the Heart. By Henri Vaquez. Translated by George F. Laidlaw. 743 pages. Illustrated. Review copy by courtesy of the publishers, W. B. Saunders Company. For sale by advertisers in California and Western Medicine.

This book has been the subject of almost unanimous favorable review since its appearance.

Vaquez is widely recognized as one of the valuable contributors to the literature about diseases of the heart. In the choice of subjects and in the manner of their presentation, this volume is delightful. Much of the cumbersome speculation so commonly used as padding finds no reference in this book.

The translating and editing by Doctor Laidlaw are worthy of fullest praise, and the book has the enthusiastic endorsement of our review editors.

"The Harrison Narcotic Law penalizes all addicts as criminals and degenerates," believes Oscar Dowling (Journal A. M. A.); "it does not even attempt to sep-

arate the wheat from the chaff. In theory, the law makes it impossible for addicts to get their supply of drugs. It does not distinguish between the criminal and the non-criminal. It is oblivious to human suffering; it sees the mass, but not the individual—the forest, but not the trees. On the other hand, the physician receives the human wreckage from the legal battle to repair and make whole again, if he can. His motives are humane, and society exacts this trait. He cannot understand, as a lawyer apparently can, that a law devoid of the elements of humanity can be framed. The physician, on the other hand, is interested in the individual more than in the mass. He sees the trees, but not the forest."

When an advertiser buys space he is buying the privilege of talking to an audience. The number in the audience will be determined by the degree of the publication's reader interest.—Standard Rate and Data Service.

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSÉ, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue
 San Francisco, Calif.

General hospital of 225 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. It saves the physician the trouble and inconvenience
of sterilizing his needles and syringe.

The Cutter Laboratory
Berkeley, California

Alkaline Therapy

IN DISEASED conditions foods (Fats, Carbohydrates, Proteins, Salts and Water) may be oxidized more rapidly than normal.

BECAUSE THE body stores fats, food may be withheld several days with no ill effect.

WHEN NORMAL ALKALIES are withheld, or used faster than supplied, symptoms of ACIDOSIS develop immediately.

NOT A SINGLE cell in the human body can functionate normally if the ACID-ALKALINE

equilibrium has been disturbed.

THERE IS NO therapy or treatment that will restore the patient to health until the normal ALKALINITY has been established.

TO RESTORE the NORMAL ALKALINITY it is necessary to supply the body with a carbonated alkaline drinking water containing the body SALTS AND ALKALIES in the exact proportion for assimilation.

CALSO WATER contains all the body SALTS AND ALKALIES. It is the most efficient and economical method for combating ACIDOSIS. One quart daily is sufficient for ordinary cases of acidosis. Severe cases may require two or more quarts daily.

CALSO WATER is indicated in the acidosis of: Diabetes; nephritis; toxæmias of pregnancy; cyclic vomiting of children; infections; cystitis; urethritis; headaches of high blood pressure; gastric hyperacidity; bronchial asthma; urticaria. In the preparation and post-operative treatment of surgical patients.

Calcium Deficiency

NOT ALONE for the creosote content may CALCREOSE be administered but also for its calcium content. Many physicians are prescribing calcium to overcome a calcium deficiency.

CALCREOSE is a mixture of approximately equal parts of creosote and calcium oxid that can be taken for a long time, and in comparatively large doses without apparently causing any gastro-intestinal disturbance; nor do patients object to its long continued use.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

Little Basin Ranch as a New Health Resort

The Little Basin Ranch, in the heart of the Santa Cruz Mountains, often spoken of as "Little Yosemite," and one of the most beautiful places in California, may be converted into a health resort, if plans already under way are carried out.

The ranch is within easy access of San Francisco and the Bay Region, and because of its ideal climate, it has been decided to establish a sanitarium, in the Little Basin itself, which will combine the features of a beautiful summer resort with that of a health resort.

The Little Basin Ranch consists of six hundred acres of wild mountain and valley, much of which is timbered and through which a beautiful mountain stream finds its way, supplied by numerous springs, located on the ranch. Ten acres of the valley bottom are under cultivation, planted to grapes, walnuts, and a variety of fruits and berries, while a portion of the ranch is stocked with thoroughbred Angora goats.

With this wonderful supply of mountain spring water, the fine elevation and scenery, there is no spot on the Pacific Coast more ideal for the development of a project such as the proposed resort.

Those interested in a project of this nature may secure information by addressing CALIFORNIA AND WESTERN MEDICINE, Box No. 950.

Parenchymal Rales in Pulmonary Tuberculosis—According to E. H. Bruns, Denver (Journal A. M. A.), showers of fine and medium rales of equal size, occurring at the end of a full inspiration, or the so-called coughing rales which occur when the patient forcibly breathes out, gives an expiratory cough, and immediately breathes in, are not due to the bubbling of secretions in the alveoli or bronchial tubes, nor are they necessarily associated with abnormal secretions in these structures. Such rales are not always associated with active inflammatory processes in the pulmonary parenchyma or bronchi, and must be distinguished from tracheal, bronchial, cavity and pleural rales. Parenchymal rales cause the most confusion. They may be due to pneumonia, fibrosis, atelectasis, pleurisy, etc., and cannot be said to be associated with any particular disease or pathologic condition. Showers of rales usually elicited only by cough and heard over the upper parts of the lungs are unquestionably the most reliable physical sign for the detection of tuberculous lesions. The significance of these rales as a criterion of manifest tuberculosis and the character of the lesions will depend on other clinical findings—history, symptoms, sputum, roentgen-ray examination. A period of observation may be necessary in order to arrive at a definite diagnosis. In studying the progress of a case and in deciding whether a tuberculous process is progressing or undergoing retrograde changes, the persistent occurrence of this type of rale is not a conclusive sign unless correlated with other physical signs and clinical findings.

The Diagnosis of Blindness—From a survey by Edward Jackson, Denver (Journal A. M. A.), of 704 eyes blind, or near blind, from all the common causes of blindness, this fact stands out: Except in amblyopia, congenital or associated with squint, blindness is always associated with objective changes that declare the sight has been greatly impaired, and often furnish the most important evidence of how great that impairment is.

1. A view of the washroom, showing "American" Cascade Washers.
2. "American" Flat Work Ironers at the Jefferson Hospital laundry.
3. The battery of "American" Prim Presses.

Forty-four cents a Week

... the cost per person at the Jefferson Hospital laundry

At the Jefferson Hospital, Philadelphia, it costs 44c per week for the laundry of each person.

There are in the hospital 473 patients and 250 employees, a total of 723 persons.

The cost per month for labor, supplies and power for operating this "American" equipped hospital laundry is \$1273.13. This means \$1.76 per person per month, or, as stated above, 44c per person per week.

Modern hospitals everywhere are installing their own laundry departments,

where the work is done under the direct supervision and according to the standards of the institution. What

"American" equipment is doing at the Jefferson Hospital, it will do for you as well.

Write us today for full information on this and other representative installations. Our corps of laundry experts will advise you concerning any question of laundry operation

or installation, and will put at your disposal figures gathered in experience extending over many years.

List of "American" equipment at the Jefferson Hospital:
 3—42x84" Cascade Washers, motor-driven.
 1—42x72" Cascade Washer, motor-driven.
 5—30" Extractors.
 2—6-Roll Flat Work Ironers.
 2—40x94" Vento Tumblers.
 6—Prim Presses.

HANOVIA

*Pioneer in
Quartz Light
Therapy*

FOR SYSTEMIC *and* ENDOCRINE DISORDERS

Considerable success has been reported for the use of Quartz Light in the treatment of Neurasthenia, Anaemia, Carbuncles, forms of Tuberculosis, Neuralgia, Neuritis, protracted convalescence and related general conditions.

The application of this therapeutic

modality is rendered particularly effective by the ALPINE SUN LAMP, which has been scientifically designed in accordance with the findings of clinical usage. Easily manipulated and adjusted, its mechanical construction assures a wide range of adaptability to the requirements of everyday practice.

Like the other HANOVIA LAMPS, the KROMAYER and LUXOR, the ALPINE SUN LAMP has the entire quartz mercury anode type burner which produces the maximum intensity of ultra violet rays with longer therapeutic life and lower operating cost.

ALPINE SUN LAMP

STATE

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

Another Journal Adopts Council Standards—Year by year the Council on Pharmacy and Chemistry continues its efforts for the rational use of drugs. Carried on with the unselfish gift of time and thought by Council members, this work represents a devotion to professional ideals that should arouse the enthusiastic support, not only of all physicians, but of other scientists and laymen as well. Slowly but surely such recognition is coming. The resolution endorsing the Council's work, signed by every member of the House of Delegates at the San Francisco session in 1916, is only the official record of the increasing support and encouragement being given by individual members of the profession. On such support the Council must, in the last analysis, depend for the complete success of its efforts. Practically every medical journal of standing refuses today to accept advertisements of pharmaceutical preparations that have not met the Council's requirements. In this *The Journal* is naturally the pioneer, but its lead has been followed by all official organs of the various state medical associations, with the notable exception of the *Illinois Medical Journal*. The difficulty of financing a strictly professional journal is, no doubt, in a great measure responsible for the failure of some publications to close their advertising columns to any but Council-accepted pharmaceutical products. That the best of these journals, however, desire to support the Council, is shown by a letter just received from the business manager of the *Long Island Medical Journal* announcing the arrival of the hopefully anticipated time when his publication could afford to solicit advertising only from manufacturers of products that meet Council requirements. This journal is the official organ of the Associated Physicians of Long Island. It is a welcome addition to the ranks of supporters of the Council's efforts for the prevalence of rational therapeutics. Henceforth only such pharmaceutical products as are accepted for inclusion in *New and Non-official Remedies* will be advertised in the *Long Island* publication. If physicians will limit their prescriptions to such products in addition to those that are in the *Pharmacopeia*, medical publishers and progressive manufacturers will appreciate the encouragement.—*Journal A. M. A.*, August 29, 1925.

Constipation, Proctis, Paralysis and Atrophy indicate the use of The Wantz Multiple Wave Generator—a New Physiotherapy Unit

Built to Physiological Specifications

Another Milestone in Standardized Physiotherapy Is Reached

When we say that the Wantz Multiple Wave Generator is “different,” we mean *radically different* from any apparatus hitherto used for the administration of sinusoidal and galvanic currents in physiotherapy.

Never before has it been possible for the physiotherapist to so perfectly control the form and frequency of the sinusoidal wave, and the intensity of both sinusoidal and galvanic currents. The extraordinary flexibility, the simplicity of control, and the true quality of currents delivered by the Wantz Multiple Wave Generator,

prove conclusively that another milestone in *standardized* physiotherapy has been reached.

Physicians who are not familiar with the nature of these currents and their value in the treatment of many conditions encountered in everyday practice, may avail themselves of reprints of authentic articles, issued by our Biophysical Research Department, explaining the physiological effects and quoting clinical experiences in the use of sinusoidal and galvanic currents. Simply fill out the coupon below.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

E. Bilhuber, Inc.—Theocalcin; theocalcin $7\frac{1}{2}$ grain tablets.

Scarlet Fever Streptococcus Antitoxin Concentrated (Globulin)—P. D. & Co.—A scarlet fever streptococcus antitoxin prepared from the serum of horses treated with subcutaneous injection of toxic filtrates from cultures of scarlet fever streptococci, and also with intravenous injections of the streptococci themselves. Each cc. neutralizes from 35,000 to 40,000 skin test doses of scarlet fever toxin. The product is marketed in packages of one syringe containing 2.5 cc., and in packages of one syringe containing 10 cc. Parke, Davis & Co., Detroit. (Journal A. M. A., August 8, 1925, p. 437.)

Diphtheria Toxin-Antitoxin Mixture 0.1 L.—A diphtheria toxin-antitoxin mixture (New and non-official Remedies, 1925, p. 333), each cc. containing 0.1 lethal dose of diphtheria toxin neutralized with the required amount of diphtheria antitoxin. Marketed in packages of three 1 cc. vials; in packages of one 30 cc. vial; in packages of ten vials, each containing three doses. Eli Lilly & Co., Indianapolis.

Typhoid Mixed Vaccine, Prophylactic and Therapeutic (New and Non-official Remedies, 1925, p. 360).

—This is also marketed in packages of three 1 cc. vials. Eli Lilly & Co., Indianapolis.

Germicidal Tablets of Potassio-Mercuric Iodide (P. D. & Co.)—Tablets containing potassium mercuric iodide, potassium iodide and sodium bicarbonate, colored blue. (For a discussion of the actions, uses, and dosage of potassium mercuric iodide, see New and Non-official Remedies, 1925, p. 239.) This product is supplied in two forms: germicidal discs of potassio-mercuric iodide No. 2 (P. D. & Co.), each tablet representing mercuric iodide

$\frac{3}{8}$ grain, potassium iodide $\frac{3}{8}$ grain, and sodium bicarbonate 16 grains, and germicidal discs of potassium mercuric iodide $1\frac{1}{2}$ grains, potassium iodide $1\frac{1}{2}$ grains, and sodium bicarbonate 45 grains. Parke, Davis & Co., Detroit. (Journal A. M. A., August 15, 1925, p. 517.)

Smallpox (Variola) Vaccine (Glycerinated) (New and Non-official Remedies, 1925, p. 342)—This is also marketed in packages of one tube. E. R. Squibb & Sons, New York.

Tetanus Antitoxin—Lilly (New and Non-official Remedies, 1925, p. 333)—This is also marketed in syringes containing 10,000 units. Eli Lilly & Co., Indianapolis.

Tetanus Antitoxin (Purified) (New and Non-official Remedies, 1925, p. 333)—This is also marketed in packages of 20,000 units. E. R. Squibb & Sons, New York.

Novarsenobenzo-Billon, 0.15 Gm. Ampules; 0.3 Gm. Ampules; 0.45 Gm. Ampules; and 0.75 Gm. Ampules. (New and Non-official Remedies, 1925, p. 50.) Powers-Weightman-Rosengarten Co., Philadelphia.

Bismosol—A solution of potassium sodium bismuthotartarate (containing 35 per cent bismuth), 10 Gm.; piperazine, 0.3 Gm., in an aqueous solution of glucose sufficient to make 100 cc. Bismosol is proposed as a means of obtaining the systemic effects of bismuth in the treatment of syphilis (Bismuth Compounds, New and Non-official Remedies, 1925, p. 73). Bismosol is administered intramuscularly. It is supplied in ampules containing 1 cc. Powers-Weightman-Rosengarten Co., Philadelphia.

Pasteur Antirabic Preventive Treatment (Harris Modification)—Lilly (New and Non-official Remedies, 1925, p. 343). Supplied in emulsion in syringes ready for use. The package containing the first seven doses is sent from the nearest Lilly depot; the second package, containing the last seven doses, is sent out from the home office. Eli Lilly & Co., Indianapolis. (Journal A. M. A., August 22, 1925, p. 584.)

E. R. Squibb & Sons—Insulin (Squibb), 10 Units, 10 cc.; 20 Units, 10 cc.; 40 Units, 10 cc.; 80 Units, 10 cc. Smallpox (Variola) Vaccine (Glycerinated) one tube. Tetanus Antitoxin Purified, 20,000 Units.

Parke, Davis & Co.—Mercurosol Solution; Neo-Silvol Ointment, 5 per cent; Neo-Silvol Vaginal Suppositories; Scarlet Fever Streptococcus Antitoxin Concentrated (Globulin). P. D. & Co.

SOLVE YOUR INFANT FEEDING PROBLEMS BY USING

Dr. Abt's Electric Breast Pump

Reproduces the Infant's Nursing

Rapidly Stimulates Milk Secretion

Saves Many an Infant's Life

References and testimonials from leading hospitals and doctors throughout the country.

See Article on use of this pump, page 728, June, 1925, issue California and Western Medicine.

An innovation of incalculable value in the practice of

OBSTETRICS and PEDIATRICS

Establishes Milk in Dry Breasts.
Relieves engorged breasts painlessly.
Empties breasts completely.
Entails no breast infections.
Eliminates many breast injuries.
Works painlessly on sore nipples.
Beneficial in case of inverted nipples.
Very effectively used by wet nurses.
Most aseptic means of milk expression.
Saves much time and work to nurses.

Hospital and Surgical Supplies — Wholesale and Retail

RIEBER

Now any doctor can afford to be his own Radiographer!

The price of the Rieber X-Ray Unit is \$1500.00 F.O.B. San Francisco.

It is sold if desired, on easy terms—for as little as \$500.00 down and the balance divided up into equal monthly payments over a year's time.

Think of it in this way:

"Here is a compact, safe, complete, time proven fluoroscopic and radiographic unit.

It is the simplest and safest of all X-Ray units to operate. With it I can make visual or photographic diagnosis of any part of the body at any time.

The tilting table is so counterbalanced that it can be swung (without motor or crank) to any one of 11 positions from vertical to 15 degrees Trendelenburg.

It is guaranteed electrically and mechanically for one year. It operates direct from any 110 Volt AC light socket.

If I had to borrow the entire purchase price of this machine, at six per cent, it would cost me \$90.00 a year—25c a day."

You can see where an X-Ray unit like this will earn you fifty times 25c a day!

We have a well written, well illustrated twenty-four page brochure, describing the Rieber X-Ray Unit. We'll gladly send you a copy without any cost or obligation if you'll mail the coupon below.

SANTA BARBARA COTTAGE HOSPITAL

"A Splendid Hospital in an Ideal Location"

Location—Santa Barbara, California, where ocean and mountains meet. Climatic conditions are perfect.

Metabolic Department—Diabetes and Metabolic Diseases are made a specialty.

Roentgen and Radium Department—Complete equipment for treating any malignant or non-malignant condition.

Cardiac Department—The equipment of this department, as well as the location of the hospital, makes conditions excellent for patients suffering from cardiac disturbances.

School of Nursing—The diversity of the work done by the hospital offers exceptional inducements to the prospective student. The Louise Savage Knapp Hall for Nurses, where the students live, is not surpassed in California.

The Squibb Diphtheria Group

SCHICK TEST SQUIBB is a reliable diagnostic test for susceptibility to diphtheria. A safe guide in determining the need of Toxin-Antitoxin immunization.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE SQUIBB—New Formula (each Cc. represents 0.1 L+dose of diphtheria toxin)—establishes an active immunity against diphtheria, lasting three years or longer. As easy to administer as typhoid vaccine. Avoid protein reactions by using only Diphtheria Toxin-Antitoxin Squibb, New Formula.

DIPHTHERIA ANTITOXIN SQUIBB is isotonic with the blood. Small bulk, with a minimum of solids, insures rapid absorption and lessens the dangers of severe anaphylactic reaction.

E. R. SQUIBB & SONS, NEW YORK
MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858.

Adapted to Breast Milk

The Anti-Rachitic Property of S. M. A.

EARLY in the experimental work on S. M. A., cod-liver oil was recognized in its important double role as a source of fat soluble "A" growth factor, and as a preventive and cure of rickets. *Ever since 1914*, there has been incorporated into the fat of S. M. A., an adequate amount of cod-liver oil. From the very beginning, too, only the highest quality of cod-liver oil has been used.

Thousands of physicians are prescribing S. M. A. with excellent results. They are assured that the infant automatically has an adequate amount of cod-liver oil to prevent rickets and spasmophilia. They recognize this anti-rachitic property as only *one* of the *many* sound nutritional principles embodied in S. M. A. Samples and literature sent upon request.

S. M. A. is manufactured by

Individualized Infant Feeding

There are more babies fed on fresh cow's milk than any other artificial food.

A vast majority of these babies are fed according to the physician's instructions to the mother.

A large number of these physicians use *Dextri-Maltose* as the modifier.

MEAD'S INFANT DIET MATERIALS

are appreciated by all physicians interested in pediatric work.

It is well worth while to every physician to write for our *Pediatric Tool Kit*.

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the method of presenting their subjects. It is believed that the author's presentation determines to no small degree the value of his conclusions.

Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented as little disturbed as possible by the editors.

However, the right to reduce or reject any article is always reserved.

Carl H. Greene, Charles S. McVicar, Waltman Walters and Leonard G. Rowntree, Rochester, Minn. (Archives of Internal Medicine, October 15), report investigations on "Functional Tests in Cases of Carcinoma of the Liver and Biliary Tract." They concluded that:

"There are definite limitations to the use of functional tests in the study of hepatic disturbances, and in our experience the extreme difficulty attending the early clinical recognition of malignant involvement of the liver and biliary passage was again manifest. We believe that the serum bilirubin and the phenoltetrachlorophthalein tests are of clinical value in the early diagnosis of carcinoma of the liver and biliary tract."

"Every once in a while we run up against a fairly competent doctor who is a natural crook, and should be trusted as far as you could throw a bull by the tail. Right on the heels of that, we may come into contact with a member of the clergy who naturally is a hypocrite and a crook by instinct, and then we think, 'Oh, well, the medical profession isn't so bad after all.'"—(*Jour. Indiana Med. Assn.*)

In banquets remember that you entertain two guests, body and soul: and whatever you shall have given to the body you soon eject, but what you shall have given to the soul, you keep always.—*Epictetus.*

Fruits for Non Sugar Patients

Fruits may now be prescribed for non-sugar diets, even when fresh fruits are not available.

Nutradiet canned fruits are the best quality fruits—the famous S & W standard of quality—packed without syrup.

Instead of sugar, Nutradiet fruits are canned in sterile water or natural juice. And a part of the natural sugar passes into the water after canning, leaving Nutradiet fruits with even less sugar than the fresh fruit.

Chemical analyses of Nutradiet fruits will be sent gladly on request. Also list of grocers where Nutradiet fruits may be purchased.

[[Nutradiet salt-free vegetables
are packed without salt or sugar.]]

DIFFERENCES IN BIOLOGICAL PRODUCTS

S*SOME* physicians doubtless assume that all biological products, by whomsoever made, are more or less uniform in safety and potency because biological manufacturers are compelled to operate under government license and regulation. But physicians themselves are also licensed and regulated by the State. Does this mean that all physicians possess a like degree of skill? Is there no difference between them?

Between one biological product and another the widest possible variation is frequently exhibited. The government merely prescribes minimum requirements. Between the minimum and the maximum is a wide range. *Tolerable* products are often far distant from *superior* products.

Take bacterial vaccines. In our laboratory the bacterial cultures used to produce vaccines bear a strict clinical relationship to the disease for which each vaccine is intended. Cultures entering Furunculosis Vaccine, for instance, actually come from furunculosis cases.

Into the manufacture of each vaccine, moreover, enters a number of strains of the same organism in order that the maximum of potency may be reached. Above all, the cultures used in our vaccines are carefully tested to determine their power to stimulate the formation of antibodies. We are able to determine beyond question the antigenic value of many bacterial cultures by the daily production of serums on a large scale.

In the manufacture of all our biological products potency, purity, and safety are kept steadily in view. The most stringent rules of procedure prevail at every step. Chemical, biological, and bio-chemical tests are constantly used to assure the practitioner that any serum or vaccine turned out in this laboratory can be depended upon to do what is expected of it.

May we not hope that you will specify "P. D. & Co." on your prescriptions for biological products?

INSULIN · LILLY

TWO NAMES ALWAYS ASSOCIATED

In the minds of diabetic specialists in the United States, the name Insulin is very closely associated with the name Lilly.

In May, 1922, The Lilly Research Laboratories began co-operating with The Insulin Committee of the University of Toronto in the development of a process for the manufacture on a large scale of a pure, stable, uniform, high-grade preparation of Insulin. Within a few months several thousands of the clinicians in this country were receiving from the Lilly Laboratories ample supplies of Insulin for experimental work.

ILETIN (INSULIN, LILLY)

Iletin (Insulin, Lilly) was the first preparation of Insulin commercially available in the United States.

The name Lilly on pharmaceutical and biological preparations inspires confidence because for nearly fifty years it has stood for scientific products, ethically advertised and economically distributed.

Iletin (Insulin, Lilly) is supplied in 5 c.c. and 10 c.c. ampoule vials, U-10, U-20 and U-40.

All Lilly Products are distributed through the drug trade

THE CATHARTIC ADDICT

**DESHELL
AGAR FLAKES
(American)**

So much interest has been created in the superior American made Agar used in PETROLAGAR (Deshell), that we have decided to place it on the market as DESHELL AGAR FLAKES, (American), for the physician who, in certain cases, may wish to prescribe agar.

DESHELL AGAR FLAKES (American) are produced in a modern American factory on the California coast.

They are free from impurities, sterilized, free from starch—which affords at least 25 per cent additional bulk.

DESHELL AGAR FLAKES (American) are unusually palatable.

They can be obtained on prescription from any pharmacy.

Responsibility for the prevalent self-medication by cathartics lies largely at the door of the medical profession. The physician in general has not impressed on the public the fact that dosing with cathartics is more likely to cause constipation than to cure it.

The cathartic acts by chemical irritation. It hurts the bowel in order to cause a forceful, violent movement. As a result of the violent exertions, the muscles are fatigued, almost partially paralyzed, and lie inactive for twenty-four to forty-eight hours.

The logical method for treating constipation is a re-education of the bowel to move at a certain definite time every day. The physician must educate the patient to the necessity of this definite "Habit Time." He must instigate the correct regimen of diet and exercise.

To shorten the period of education, he can use a mechanical aid—PETROLAGAR (Deshell)—which provides a soft, oil-lubricated, bulky, easily passed stool.

PETROLAGAR (Deshell) is an emulsification of 65 per cent pure mineral oil (which is not digestible and not absorbable) and agar-agar (an indigestible cellulose material, which absorbs moisture and increases its bulk).

The agar now being used in PETROLAGAR (Deshell) is an American-made agar—a superior product, free from starch, which affords at least 25 per cent additional bulk.

PETROLAGAR (Deshell) has been accepted for *New and Nonofficial Remedies* by the Council on Pharmacy and Chemistry of the American Medical Association.

PETROLAGAR (Deshell) is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

Apply SUPERINTENDENT OF BUILDING

The Value of Organized Surgery to the Poor Surgical Risk—Frank H. Lahey, Boston (Journal A. M. A.), discusses pre-operative preparation, anesthetist, assistants, and operative nurses. He says: "A surgical organization is applicable to any situation in the practice of surgery, but must be necessarily modified the less centralized it becomes, and, conversely, the organization may be more closely knit, and more highly organized the more centralized it is. We were led to centralization of surgery in the beginning by the needs of the bad risk cases coming to our clinic, and from the success and satisfaction resulting from this centralization we have been led gradually to the almost complete centralization of our surgery. The only exceptions are emergency surgery and the necessity of supplying consulting surgeons to a few suburban hospitals, which is done by the junior members of the clinic. We realize that there are trying community difficulties for the person endeavoring to organize his surgery; that early in a surgeon's career it is not possible to afford even a small organization, and that in certain communities it requires courageous enthusiasm up to the point of jeopardizing one's practice to undertake organization, to refuse to operate on patients in outlying hospitals and communities, to reject the services of physicians close to the patient but undesirable from the point of view of marked efficiency, and to refuse the request to operate on patients when they may be close to their families at the expense of increased risk. There are, indeed, innumerable natural and artificial obstacles in the path of the development of surgical organization; but it is in process of supplanting unorganized surgery; it gives to the poor risk patient better chances of recovery; it tends to make better surgeons earlier in life; it produces greater progress in surgery; it is applicable, with temporary modifications, to any field of surgery from that in a large and prosperous community to that in rural communities of limited financial resources; it lends added pleasure and enthusiasm to the practice of surgery, and it develops means, measures and methods that are of definite and distinct benefit to the so-called poor risk patient."

They Say—

Words of Appreciation, From the Profession on Medical Protective Service

"This opportunity affords me great pleasure to thank The Medical Protective Company for their clean, businesslike, very thorough, detailed methods of defense. You certainly spared no effort, nor expense from the start and made every move count to circumvent it practically and legitimately.

"The very best firm of legal talent in the state was suggested by you, and after consulting my wishes in the matter, with my approval was retained. They also met the height of anticipation, by realization in action.

"I cannot speak too highly, nor emphatically, of the manner in which I was defended by the Company, and the ethical methods employed in my behalf throughout this litigation. Even my more sensitive and critical friends lauded the Company throughout the entire period. Needless to add, perhaps, that should necessity compel me to continue the practice of my honored profession another eighteen years, I would not be without your constant protection one of those years, just for the sense of security my last seven or eight years with you have been, and the ease of mind which it affords one from the envious, the nefarious blackmailers, the ever-grasping base character, assassins and what not that infest and permeate more or less, most every community and not the least, the shyster lawyer. Ordinarily one of these elements is enough but a combination as in this case, preying on one more fortunate in worldly possessions is hard to beat, but you did it."

* * * *

"Am enclosing my check for Twenty-one Dollars, renewal for April '25 to April '26—and I want to say, I do not know of any place I could place the like amount that would give me as much satisfaction and pleasure.

* * * *

"I certainly do appreciate your efforts in my behalf. I insure against everything, AND THE CHEAPEST INSURANCE I CARRY IS IN YOUR WONDERFUL COMPANY."

* * * *

"Whenever you fail to receive my renewal promptly, there will be a small piece of crepe on the office door."

What is Nonspi?

NONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless, NONSPI need be applied, in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

Activities

Mount Zion Hospital Staff announces a weekly schedule of ward rounds, operative clinics, and special exercises, including a weekly staff conference to consider clinical problems of unusual interest. Visiting and out-of-town physicians are cordially invited to attend these exercises. Details of weekly programs may be obtained by telephoning West 7200 (Mount Zion Hospital), Franklin 1507 (S. F. County Medical Association), and Douglas 62 (California Medical Association). Following are the days on which the special exercises are held:

Monday 9:00 a. m.—Medical Ward Rounds. Samuel H. Hurwitz, M. D.

Tuesday 8:00 a. m.—Weekly Staff Conference.

Tuesday 9:00 a. m.—Urologic and Cystoscopic Examinations. Louis Clive Jacobs, M. D.
 Wednesday 8:30 a. m.—Operations. Charles G. Levison, M. D., and Harold Brunn, M. D.
 Thursday 8:30 a. m.—Eye, Nose and Throat Operations. Aaron Green, M. D., and Herbert Cohn, M. D.
 Thursday 9:00 a. m.—Medical Ward Rounds. Emil O. Jellinek, M. D.
 Friday 8:30 a. m.—Clinical X-Ray Conference. Lloyd Bryan, M. D.
 Friday 9:00 a. m.—Pediatrics Rounds. E. Chas. Fleischner, M. D. and Jos. Sampson, M. D.
 Friday 9:30 a. m.—Prenatal Clinic. Louis I. Breitstein, M. D.

Troy Laundry Machinery Co.,
East Moline,
Ill.

Gentlemen:

You perhaps will be pleased to know that the 30" x 42" Service Drying Tumbler, Belted Motor Drive, which we purchased thru your representative Mr. Gleason sometime ago has been a treasure. We have been forced to crowd it to its utmost capacity but to date we have not had the slightest trouble with it.

We believed when we made our choice that it was a wise one, but we can truthfully say today that we were wiser than we thought.

We sincerely thank Troy Laundry Machinery Company and Mr. Gleason in particular for persuading us to make this efficient purchase.

Sincerely yours,

THE CHILDREN'S HOSPITAL

Arthur O. Bauss
Gen'l Superintendent.

AOB:MD

For the small hospital laundry no better drying tumbler is built than the Troy Service Dryroom Tumbler. The above letter from Mr. A. O. Bauss is convincing proof that the machine "delivers the goods" and that Troy service and equipment is a wise choice.

Troy laundry machinery has proved equally satisfactory in many other representative hospitals and institutions. A staff of Troy experts is always ready to advise you concerning any laundry problems which you may have. This service is offered without any obligation.

The Dietetic Value of Gelatine

Receives High Recognition

The edition (6th) of "Diet in Health and Disease" by Dr. Julius Friedenwald and Dr. John Ruhräh, published by W. B. Saunders Company, Philadelphia, contains the following tribute to the value of Gelatine in feeding infants and children:

JACOBI in 1879 suggested the use of Gelatine in infant feeding, and it has been used some ever since, but only recently has the real value of Gelatine in the diet been made more widely known. It is very useful in rendering milk mixtures more digestible, preventing both gastric and intestinal indigestion by preventing the large, hard curds. Where the appetite is poor, the addition of Gelatine makes the milk more palatable for some children. It is of value in infants who regurgitate or vomit their food, in diarrhea particularly where there is putrefaction. It is useful where gas is formed, either in the stomach or the intestines, and in fermentative conditions in general. It is useful in preventing colic in some babies, and in the breast fed may be given in solution just before feeding. In infants who are constipated and who have large, hard stools which do not adhere to the napkin, the addition of Gelatine to the formula usually corrects the difficulty. It is of great value in celiac disease, not only in supplying additional much needed food, but in correcting the accompanying indigestion. In malnutrition the addition of Gelatine to the dietary is of great value, as it is in those who have lost weight through operations, fevers, or other illnesses. It has also been suggested in scurvy."

Knox Sparkling Gelatine—highest quality for health—is the purest form of plain granulated Gelatine, produced by the most scientific methods, and under constant bacteriological and chemical laboratory control. It contains no artificial flavoring—no sweetening.

In prescribing Gelatine for the diet, physicians should be extremely careful to specify *Knox Sparkling Gelatine*.

FREE—TO PHYSICIANS AND HOSPITALS

The physician's reference book of nutritional diets with recipes will be sent free to physicians or hospitals, upon request, if they will address the Knox Gelatine Laboratories, 417 Knox Ave., Johnstown, N. Y.

In addition to the family size packages of "Plain Sparkling" and "Sparkling Acidulated" (which latter contains a special envelope of lemon flavoring), Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use.

KNOX

SPARKLING GELATINE

"The Highest Quality for Health"

Free from harmful acidity, artificial coloring, and synthetic flavoring.

Development of Our Knowledge of Tuberculosis. By Lawrence F. Flick, M. D. 738 Pine Street, Philadelphia, 1925.

"The Chiropractic Initiative Proposition—As the proposal now stands, submitting to the people of Ohio at the November election the question of a separate licensing board for chiropractors is opposed by all earnest public health groups and by the Licensed Chiropractor Society of Ohio as well. The Ohio State Medical Journal says that the provisions of the proposal would permit the so-called 'National Board of Chiropractic Examiners, a paper organization,' sponsored by the Palmer School of Chiropractic, to grant licenses by reciprocity; that is, this particular school would be able to set standards for chiropractors in Ohio. The initiative bill was rejected by the general assembly, February 26, and a supplementary petition filed with the secretary of state, May 29, two days after the expiration of the ninety-day period provided by the constitution of the state. If voted on favorably in November by the people, this proposal would admit chiropractors to all the privileges of physicians, destroy the value of vital statistics, abolish the single board of licensure and allow the state to be overrun by a horde of cultists."—*Federation Bulletin*.

All thinking doctors know that more information comes to a medical editor than to any other physician. We try to intimate with sufficient clarity to our readers dangers that lurk by the wayside. It will pay any doctor in self-interest to read intelligently the brief paragraphs in California and Western Medicine.

REX DUNCAN, M. D., Medical Director

Universalizing Breast-Feeding in a Community—

Frank H. Richardson, Brooklyn (Journal A. M. A.), states that universalizing breast-feeding in a community has become standardized. This procedure consists of three essentials. 1. There must be a group of physicians who are convinced of the overwhelming superiority of breast-feeding over bottle-feeding; who believe it attainable for the vast majority of infants, and who are familiar with a working technic for making breast-feeding possible for the individual child. There must be the co-operation of the birth-recording department or bureau of the community, whether of the city or of the state department of health. There must be an organization controlling sufficient nurses trained in the technic of breast-feeding, to visit each newly made mother as soon as a birth certificate is filed, in order to instruct her in the desirability of keeping her baby on the breast, as well as in the way to accomplish this. These three fundamentals have formed the basis of the Nassau County (New York) breast-feeding demonstrations in 1923 and 1924—the first large-scale piece of work along this line. The New York State Department of Health, which was interested in putting this on as a demonstration of what might be done anywhere in the state, supplied in its own machinery the second and third essentials. The Brooklyn Pediatric Society, with which there was the closest co-operation throughout, furnished the first essential, viz., the group of physicians vitally interested in the spread of breast-feeding. The demonstration dealt with 2815 babies. Nineteen-tenths of the mothers succeeded in nursing their babies for one month, and two-thirds of them did so for seven months. The infant mortality rate of the 2815 babies studied was 49 per thousand. That of Nassau County for 1923, the year of the active campaign, was 64. That of Nassau County for the years 1920, 1921, and 1922, the years preceding the experiment, was, respectively, 70, 67, and 78, with an average of 72. That of Nassau County for the year 1924, when the "hangovers" only were being visited, was 74.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

HOW TO MAKE A DOCTOR

AN UNUSUAL SYMPOSIUM ON THE ESSENTIALS OF MEDICAL EDUCATION

By PRESIDENT RAY LYMAN WILBUR, M. D., *Stanford University*; WILLIAM ALLEN PUSEY, M. D., *Former President American Medical Association*; DAVID A. STRICKLER, M. D., *President Federation of State Medical Boards*; N. P. COLWELL, M. D., *Secretary Council on Medical Education and Hospitals, American Medical Association*; FREDERICK C. ZAPFFE, M. D., *Secretary Association of American Medical Colleges*; J. S. RODMAN, M. D., *Secretary National Board of Medical Examiners*; WILLIAM OPHULS, M. D., *Dean Stanford University Medical School*; L. S. SCHMITT, M. D., *Acting Dean University of California Medical School*; PERCY T. PHILLIPS, M. D., *President California Board of Medical Examiners*, and PERCY T. MAGAN, M. D., *Dean College of Medical Evangelists. With an introduction by the Editor of CALIFORNIA AND WESTERN MEDICINE*

INTRODUCTION

By WILLIAM EVERETT MUSGRAVE, *Editor*

AT THE 1924 session of the Association of American Universities, President Ray Lyman Wilbur delivered an address on "Maintaining Standards Without Excessive Standardization." This address forms the basis of the following remarkable symposium, written in the order in which it appears. All discussants, therefore, had before them not only a copy of the original address, but in addition what each preceding discussant had said. This symposium, therefore, is no mere extemporaneous ramble, but represents the deliberate conclusions of a galaxy of medical teachers upon a vital problem not heretofore brought together in such consecutive order. Sustained and prolonged but unsuccessful efforts were made to secure the co-operation of President W. W. Campbell, University of California. All others who were invited lent their enthusiastic co-operation.

DOCTOR WILBUR, in his original address, which is too long to reproduce in full, said:

"'Maintaining standards' were the words that symbolized academic arrival a few short years ago. Now the very word 'standard' brings with it a sense of reproach because, in the efforts arbitrarily to force certain standards upon education, the life juices of intellectuality and initiative were being squeezed out and the divine right of the human to be different and yet achieve success was in danger of being denied in the very place where advance comes best with a large measure of freedom."

"The attempt to measure results and to make choices and yet remain responsive to new ideas, new discoveries and new methods of instruction has tangled our whole educational scheme, particularly when, as in medicine, legislation, with its crippling and crystallizing tendency, has entered the field. Parrot teaching where the fountain pens of the student reproduce the record, often an old one of the teacher, flourishes where set standards, set examination questions and conscientious but unimaginative examiners keep up the bars against the unfit."

"The history of medical education during the past quarter of a century offers an unusual illustration of the losses and gains possible with the projection into a field of science and into a profession of educational standards based upon new ideals and new demands."

"With the adoption of the standard curriculum through the efforts of the American Medical Association there developed a nationwide inspection of the facilities of medical schools and the methods used in instruction. Standards were set up for equipment, laboratory space, number of beds and out-patients per student, etc."

"At the same time a general movement for an improvement in the legislation of the various states in connection with medical practice brought about the adoption of medical practice acts with very definite

required standards set up in the law. These were administered largely by boards made up of men belonging to the profession. In a number of states the standards set by the Association of American Medical Colleges became automatically the standards of the state for those obtaining a license to practice medicine and surgery, and a unique situation was developed by which, when the Association of Medical Schools had joined in a common action regarding the curriculum, it became the law in certain of the states. Throughout this whole quarter century there was a steady advance in science, in the field of medicine, and a complete revolution of viewpoint in the teaching and in the practice of medicine."

"The medical curriculum, although practically confined within the limits of four years, took on in a number of schools a fifth or intern year. The absorption of practically all the time of the student in set tasks was most unsatisfactory. The medical student upon graduation was gorged with the stuffing he had received, but was not ready for the actual practice of medicine. At the same time medical faculties found themselves teaching to meet the requirements of state board examinations. They found it necessary to keep up a certain number of schedule hours in subjects that no longer needed emphasis in the undergraduate medical work because of the legal requirements. The Frankenstein of medical standards, built with so much enthusiasm and devotion to ideals, began to destroy individual initiative and to stand in the road of progress, bringing stasis in a stream in which ever more rapid motion was necessary."

"Subjects once introduced, although perhaps of decreasing importance, still had their adherents. The tenacity of the teacher in hanging on to all that he can get of the student's time is one of his most laudable but troublesome traits. The dead hand of the past maintains a strangle-hold on the curriculum. What has been must always be until in the usual faculty wrestling match the new wins a foothold."

"The handling of the pre-medical requirements, as well as those of the medical school, became one largely of figures. Addition of numbers with proper titles and to obtain proper totals became the object of deans everywhere. That this method had its ridiculous side was evidenced when the osteopathic and other similar schools were found capable of multiplying and adding faster before legislative committees in presenting curricula of their schools than could the so-called regular schools. Standards had resulted in a situation where quantitative measures became predominant. The cubists in medical training began to find a ready opening for short-cuts and to insist that theirs was the real art and that fundamental training in anatomy, etc., belonged to the past."

"We cannot say that this situation has passed, but there are evidences of a change in viewpoint. There is an increasing effort to diminish the number of actual required schedule hours, a willingness to put forward optional and elective courses and an earnest effort to reduce the work of the medical curriculum to the more fundamental subjects, leaving the specialized or more technical ones for work

beyond the M. D. degree. More choice and less imposition is now the tendency."

"It seems to me that it is quite clear that the basis of university and professional training should be one of maintaining standards. The great difficulty is to define these standards and not to consider standards, quality and progress as synonymous terms. Choices in every field of education are difficult, and choices made by the teacher of the material in the subject in which he is interested for the instruction of students becomes of paramount importance. When these choices must be made upon an artificial basis because of some requirement which the student must eventually meet, we have interfered materially with the individual initiative and possible inspiration of the teacher concerned. It is particularly because of this that required set standards demanding absolute fact knowledge or knowledge of technique should be kept down to the absolute minimum."

"Since, if we are to maintain standards without overstandardization, we must enhance the quality of the work, magnify the initiative of the teacher and enlarge the capacity of choice by the student, we must at the same time have some solid form of examination of a character to test the ability of the student to carry on in the work which he has begun, rather than a mere memory test. It is inevitable that such examinations should be insofar as possible of a practical character and that they must be prepared by those who are at the top, the greatest experts; those who view their particular fields from the standpoint of fundamental principles, rather than of the class so prone to make out examination papers who seek for exact information in the more minute forms of knowledge. The full advantage can only come if the teaching profession of the country agree to do less work for their students."

"In building our academic structure of standards we should think in terms of stresses and strains, rather than merely visualize a more or less decorative bric-a-brac. Standards evolved by joint action of those best informed are essential for the development of students, for the protection of teachers with an excess of initiative, and for the advance of education and science in civilization. Standards set by those with high ideals are needed in every domain where knowledge is used in practical human affairs."

"In concluding may I suggest the following procedures as worthy of some thought:

- "1. Reduce rigid requirements radically.
- "2. By careful studies by experts outline central core of essential parts of required subjects.
- "3. Insist that every college student shall take at least one subject where he can obtain facts firsthand.
- "4. Hold the student to solid achievement in tasks once undertaken.
- "5. Increase the number of set papers required of students to stimulate individual work.
- "6. Provide a marking system which will serve as a basis of self-valuation to the student.
- "7. Make calendar consumption secondary to actual achievement.
- "8. For admission to the university there should be required:
 - (a) A record of scholastic achievement.

(b) The passing of an intelligence test appropriate for a student who has covered the high school period.

(c) A record of the personal qualities of the student, physical, mental and, if possible, moral. Some form of character test is particularly required.

"9. Provide a comprehensive examination at the end of the sophomore year along the lines of the college entrance board examinations, covering any four subjects, in order to test the student's capacity to go beyond elementary college work. This will provide for the gradual unfolding of the American university, beginning with the junior year, and for the development of the necessary junior colleges, and will also serve as a standardizing device in the acceptance of transfer students and of students whose courses have been irregular.

"10. The standard for the degree of doctor of philosophy should be so changed that the recipient of that degree should be freed from the necessity of taking set courses of any kind during the latter part of his work. It should be a degree conferred upon one who has done original research. Standardization of this degree so that its recipient reads certain languages and has covered certain minors and majors is a mistake. The departments recommending candidates for this degree should take full responsibility for them.

"11. *Degrees in engineering, medicine and law, once granted by a reputable university, should serve as a basis for admission to practice before the public in the domain in which the university has given certification. Those who wish to practice these professions, and who are not graduates of recognized universities, should be required to take examinations under the auspices of the state universities. The setting up of examining boards, while advantageous in many ways, has reached a point where it handicaps the development of the professions more than it helps. Either the boards must change their type of examinations, making them of a practical character, or some other device must be found to free the universities and their professional schools from the narrowing influences of rigid legal standards in the field of education.*"

These abstracts from correspondence between President Wilbur and the Editor have a pertinent bearing upon the discussion:

DR. WILBUR TO THE EDITOR—"It seems to me that with the transfer of medical education over to the universities of the country the time has now been reached when the degree of Doctor of Medicine should be protected by the universities rather than be associated with all the fads and isms that have to be recognized by state legislatures in setting up boards of medical examiners. My personal feeling is that the universities ought to assume this responsibility, that they can carry it on better than anyone else, and that through them we can get a distinct line drawn between the holders of the degree of Doctor of Medicine and all the others who make attempts of one sort or another to treat the sick."

THE EDITOR TO DR. WILBUR—"There is one point upon which I am not clear as to your meaning and that is, whether or not the assumption of educational ability by the state universities would be the limit of their responsibility and their work, therefore, auxiliary to the Board of Medical Examiners, or whether you intended to suggest that all of the duties and responsibilities relating to license, discipline and control and law enforcement in general, should be undertaken by the university with elimination of the Board of Medical Examiners."

DR. WILBUR TO THE EDITOR—"In the development of medical education in the United States the universities have assumed the responsibilities of the instruction of medical students. This is more and more true of state universities. *I feel that the M.D. degree should mean ability to practice medicine and that the certification directed by the universities that a man is ready for practice when he has that degree will do more to bring back the art of medicine than anything else.* As you fully realize, the emphasis has been so strongly upon the scientific side that the actual instruction in the methods of actual practice has suffered materially. The very diversion of this responsibility over to a state board of examiners has been often quoted to me as removing the responsibility from the medical faculties. My idea is that the universities, that is the state universities and those with well-established medical schools, should make the degree of Doctor of Medicine as granted by them mean that a man is ready for the *practice of scientific medicine*. I see no reason why they should not certify their men for the practice in the states in which they are located and why the university should not be able to work up reciprocity among the various states with well-established institutions, since the educational institutions are well posted as to the qualifications of their sister institutions. I think, too, that the National Board of Examiners should be brought into this machinery in such a way that it will take care of those with foreign or diversified training and can act as the co-ordinator where the educational standards differ as between the North and the South, etc. I feel that we will still want a board of medical examiners to protect the degree of Doctor of Medicine from encroachment by those who are not fully trained and to protect the public against the illy educated of all sorts who treat the sick. I should be rather inclined to favor a board made up partly of laymen for this purpose so that the statement of trying to control treatment could not be urged against the regular profession. It will be several hundred years, in my judgment, before we are able to develop a point of view on the part of a large part of the public unfavorable to the cure-all type of practice. Men always have wanted to be fooled, and I imagine that many of them will want to be for a long time."

Many years' experience in practice; in teaching, and as dean and executive officer of a fine medical school; hospitals, research institutions and welfare organizations, in extremely trying circumstances, and many more years of reading and editing medical manuscripts, long since has convinced this editor that *the most important things a doctor should know are not medicine at all and are not taught in medical colleges or elsewhere effectively.* These are character, sympathy, industry, charity, patience, economics, the spirit of consecrated service—in a word, *the art of medicine as it was once understood.* Medical students received much of this under the preceptor method of teaching, long since discontinued, *without providing anything to take its place.* To paraphrase: That wholesome mass service is but the lengthening shadow of a man, is particularly true in bedside medicine. It is quite as true with machine-made doctors today as it was in those days when students starved to follow and absorb the personalities of great leaders. It was more the human qualities of the immortal Osler than his scientific attainments that endeared him to his disciples and patients. Fortunately, he was super-endowed with both a knowledge of the humanities and of science. Many able medical teachers of today would be much surprised to know what it is in themselves that particularly and permanently influences the after lives of their students.

William Allen Pusey, M. D., former President American Medical Association—The sugges-

tions of President Wilbur that efforts should be made to free medical education from its strict standardization and increase the responsibility of the universities for the medical education they give are, to my mind, sound and of great practical importance. The important matter in medical education, after all, is that students should be well prepared. Under ideal conditions the proper requirements for the practice of medicine would be that the applicant for license, after character and intelligence, should have the requisite amount of knowledge, skill, and experience. How he obtained his preparation would not be a matter of essential concern. But we are not living under ideal conditions, and I have no feeling that we can go that far at the present time.

I am strongly of the opinion that it would be to the advantage of medical education if responsible high-class medical schools should have the greatest possible freedom in the teaching of medicine to their students. At the present time no such situation exists. Medical education is bound up tight to the specified requirements that have been set up by the various examining boards, largely under our direction. They specify so much of this, so much of that, and so much of the other. We are tied to a formal curriculum which not only allows the universities practically no leeway, but makes no allowance for the varying ability of students. It would conduce to the improvement in the quality of medical teaching and in medical education if we could give our students to the universities and tell them, turn them out properly prepared; how you do it is your affair.

I am entirely in accord with President Wilbur's suggestion that responsible institutions of proper standing might very well be permitted to certify their graduates to the licensing boards of their respective states and have these students accepted for license on that basis alone. That, however, is a course that is open to great abuse, as shown by our experience before thirty years ago, when medical schools practically owed their existence in many cases to the fact that their diplomas were accepted as a license to practice. It would be a matter for the individual states. If this privilege were confined to institutions of high standing it might very well strengthen the licensing situation by the effect it would have upon the licensing boards; and that is an exceedingly important matter. Medical education would be on a pretty sound basis if we got away from formalism and standardization and if the candidate for the license knew that all that would be required of him would be for him to show unquestioned competency to begin practice. It would give the able student his opportunity. It would supplant time standards, which are so expensive and so uncertain, by quality standards which are the only proper measure. It would open up to medical schools opportunity for initiative, originality and, as a consequence, progress.

In short, I believe President Wilbur's suggestions are steps in the direction of real progress in medical education which we should follow as rapidly as we are equal to them.

David A. Strickler, M. D., President Federation of State Medical Boards—The question as to how far and by whom fixed standards shall be established in the education of medical students, is a broad one involving many problems as viewed from different angles. The primary object of a medical education differs with individuals. Here, as elsewhere in education, there should be some flexibility in the course offered by our worthwhile universities and colleges. *For that large class of medical students who have as their primary object the practice of medicine, we think the first essential is stability of character, honor and integrity. In no other calling is true manhood more essential.* Two men of equal mental capacity, training and general educational opportunity are in no sense equally safe in the interest of public health or morals if one essays to major surgery or other highly specialized work without adequate technical training, while the other conscientiously prepares himself for his chosen tasks and keeps within his field of preparation. The former from within the medical profession is more dangerous to a community and does more to damn the medical profession than a dozen cultists can do from the outside. From the viewpoint of an administrator of a Medical Practice Act, we hold that for one to hold himself out as a specialist without specific preparation, is to attempt to do what he has no moral right to do, and that such practice bears specifically on the moral character of the applicant, even to the extent of denying him the right to take an examination, because not satisfied as to his good moral character.

Secondly, we would stress a close inter-relationship between study of medicine and its practice throughout the course of training. To have the first four years a disconnected study of science, with two final years devoted to clinical study is, in our opinion, a serious mistake which should not be made.

The student should be taught to constantly associate his studies with their ultimate purpose. *To be so highly trained in pure science and in scientific methods as to lose sight of the individual who is sick, is to lose an influence that the medical profession can ill afford.* I fear our present trend is too strongly inclined toward science and method, with too little thought of the individual needing care. The proper relationship between physician and patient is a complex, not learned from textbooks nor test tubes. *The days of the preceptor held much to be commended that has not been supplied by advanced educational institutions.* There is that something in all of us which demands attention to the ego. If the medical profession fails to recognize it and provide for it, there will always be those of less training in science who will administer to it, because human nature is much the same the world over.

We believe that individualism in our great institutions of learning, like initiative in the student, should be encouraged. *That present-day standardization is a leveling down instead of an upbuilding process. It inhibits initiative and retards progress.* For this reason we think it a mistake for a state to make statutory provisions for any fixed educational standards with required hours on various subjects, as is sometimes done. It should rather be the func-

tion of an educational institution to determine the details of an education which will justify the granting of a degree which it may and can protect; of the state, for purposes of licensure, to require of the educational institutions adequate time and opportunity under favorable conditions before a degree may issue.

A degree granted under these conditions supplemented by an examination, both written and practical, by a competent board of examiners would best meet the needs of the state in the interest of public health.

If the degree of M. D. were properly protected by educational institutions, and if the state insisted that only those who hold such protected degrees may be licensed or allowed to practice medicine, the Board of Examiners might be dispensed with. Unfortunately, none of these conditions holds. The degree is too often meaningless; the state frequently does not require the degree of M. D. for a license to practice the healing art, and the Board of Examiners is incompetent either by virtue of inherent weakness or statutory provisions preventing a thorough and efficient examination.

We know of no panacea for these unfortunate conditions. We suggest, as lines of worthwhile effort, wider discretionary powers to our better educational institutions with better protected degrees; closer supervision by the state of institutions authorized to teach and grant degrees within its domain, more thorough and complete examinations by state boards when necessary; broader recognition of credentials, including well-protected degrees, supplemented by National Board certificates for licensure without examination.

N. P. Colwell, M. D., Secretary Council on Medical Education and Hospitals of the American Medical Association—In his article Dr. Wilbur recognizes the need of certain standards, and points out that they should not be emphasized to the extent of having them substituted for that education and testing which are necessary to ascertain the actual knowledge possessed by the student. He shows that quantity measurements, as indicated by hours, terms, years, etc., should not be permitted to displace the methods and measures by which quality can be determined.

Few people today realize the extremely serious conditions of medical education only twenty brief years ago. In 1900 this country had over half of the world's supply of medical schools and, of the 160 then existing, only two from the standpoint of preliminary education could compare favorably with those in the leading countries of Europe; less than thirty were actually requiring a high school education for admission; a large majority were stock corporations conducted for the profit of their owners; the majority were seriously lacking in teachers, laboratories and laboratory equipment and, finally, only a small proportion had adequate relations with hospitals and dispensaries where clinical material was available which could be used for teaching purposes. The 160 schools varied all the way from those which were out-and-out diploma-mills up to those which were worthy of or possessed recognition around the world. Under such conditions, of

course, it was highly important that fairly definite minimum standards should be established, as was done by some of the more progressive state licensing boards. The establishing, in 1904, of two standards by the Council on Medical Education—one for immediate adoption and the other, the so-called ideal standard, for future adoption—brought tremendous results for good in medical education. These standards were held up, however, not as rigid requirements, but for their suggestive value, and the advances obtained were through the prompt and enthusiastic adoption of these standards by the majority of medical schools.

The changes in medical education since 1900 are such as could not be anticipated at that time. These changes, however, are but a parallel to the stupendous developments in other social and scientific fields. Indeed, the last twenty-five years have witnessed scientific developments such as have no parallel in all previous ages. Instead of the old candle-dip and the oil lamps, our homes are now brilliantly lighted with electricity. In transportation, the ox-cart, the saddle horse, the four-wheeler, and the horse-drawn street-cars have given way to the more rapid transit of electric street-cars and interurban trains. The modern boulevards and highways, the automobile, the movies, airplanes, and other improvements during the last twenty-five years have brought about marvelous and unprecedented changes in social and economic conditions. So also have our medical schools developed from the single lecture-room institution in many instances to the great campus with its multitude of medical buildings and hospitals. From only one or less full-time expert laboratory teachers on the average, there are now twenty or more in each institution. These changes have taken place in an amazingly short space of time. The skeleton structure of the greater medical teaching institution has been completed; now is the time to make the very essential internal developments and modifications.

Most prominent among the improvements in medical education is the fact that now 80 per cent are integral parts of high grade, reputable universities, and these are enforcing, with fair rigidity, an entrance requirement of two or more years of college work. There is no longer need for several of the requirements still retained in state medical practice laws, which were highly important under the chaotic conditions existing twenty-five years ago. Certain standards, indeed, are still essential, but these should not be so minutely detailed as to prevent the further essential progress in medical education. Nor should they be such as will cause an extreme hardship, if not an actual injustice, to certain exceptional students.

Responsibility for the essential changes in medical education belongs properly to and can be safely left with the officers of the medical schools. In this development, as Dr. Wilbur well points out, the student should have the chance to do for himself rather than to have so much done for him. There should be a larger provision for optional or elective courses, and the actual schedule of hours should be reduced sufficiently to allow the student to properly master the subjects to which he is assigned. These subjects, furthermore, should not only be limited to the essen-

tials of the medical training, but also should be correlated so that as principles are learned they may also be applied in the care of patients in dispensary and hospital.

At present there appears to be a tendency to deprecate the changes brought about in medical education and to forget the utter lack of standards and the chaotic conditions existing twenty-five or more years ago. *Let us not go too far in this deprecation, but rather look with thankfulness on the great improvements made and continue to strive until conditions which are still unsatisfactory have been corrected.* The steadfast purpose of medical education is to provide for humanity the best possible medical service.

Frederick C. Zapffe, Secretary Association of American Medical Colleges—As for Dr. Wilbur's paper, as a whole, I am in full accord with most of the points made, but being given the opportunity to comment on the situation generally, I shall endeavor to do so.

Most discussants seem to overlook the fact that many of the undesirable features connected with medical education today are the result of evolution. The same is true of standards. It is only comparatively recent that anyone not connected with a medical school or a state licensing board took any interest in medical education. Even the administrative officers and executives of universities that had integral medical schools apparently were only too willing to leave medical education in the hands of the medical faculty or those few in the faculty who took an interest in it. Therefore, the present-day awakening of the university officials is gratifying, although not all of them seem to grasp the full significance of everything that has been done. This statement is based wholly on the results of personal contact with university executives. As one who has been in intimate touch with this work for more than twenty-five years, I have had opportunity to see and observe. *I am convinced that much progress has been made; that the situation is becoming better year after year; that eventually enough responsible persons will become interested in medical education to work out its future and be in a position to meet new problems as they arise, and new ones arise every year.* I do not believe in fixed rigid standards, although I am convinced that we must have standards which shall serve as a starting point. If I had to set the standard for admission to medical schools, it would be based entirely on knowledge possessed and mental fitness, and not on semester hours or credits. That system is a most pernicious one and wholly detrimental to every form of education.

It is equally as bad as the antiquated requirements laid down by state examining boards because of state laws enacted many years ago that the applicant for medical licensure must have attended four annual sessions in four calendar years, making it impossible to carry on teaching in the medical school in any other way—except by subterfuge, although I do not mean to say that such a thing is being done. The pre-medical requirement can easily be fulfilled by any ambitious youngster who applies himself and puts in the required hours and secures the needed credits. That does not, however, signify

that he is fitted to enter on the study of medicine. Dr. Wilbur's suggestion to make mental tests part of the admitting machinery certainly would help tremendously to straighten out matters in this direction.

Many errors have been corrected; others will be corrected in the near future. After about ten years of deliberation and study, the present medical curriculum was evolved. It is a good curriculum, but it is not yet being enforced sufficiently well. Its greatest advantage is that it is not in any sense rigid. On the contrary, it is exceedingly elastic—and it is aimed entirely to make good doctors of medicine, not specialists—a job that should be relegated to the post-graduate schools. A recent review of medical school curricula made by me and reported on at the recent meeting of the Association of American Medical Colleges showed that much remains to be done before all the medical schools will take this so-called standard curriculum and adapt it to their particular facilities. *Whenever more co-operation is evinced between the various departments of medical schools, the hospitals, the state licensing boards and all agencies concerned in education, medical and otherwise, a more perfect curriculum will be evolved.* Why should state laws stand in the way of better medical teaching? Why should the state of mind of hospital trustees and superintendents stand in the way of better medical teaching?

Medical education is not for the individual. It is for the community. It is a part of the large educational movement in which laymen, as well as professional men, are interested because the end sought is better health. Co-operation, leaving the final working out of any plan to those most concerned with it, is what is needed at this time. Much co-operation must come from medical teachers and educators. The latter must realize that while pedagogic principles must prevail, only the medical teacher can apply these principles to medical teaching. And the medical teacher should realize, more than he does now, that he must do more real teaching which will fit the medical student for the practice of medicine. We can learn only from research; we must have research; we should do everything to foster research and to encourage men fitted for it to go into research; but what we need more than that, even at this time, is more teachers—men who are willing to devote themselves to teaching rather than to research; men who are sufficiently well trained to get all there is to get out of research and work over the result for presentation to the student.

There never can be given to teaching all the time needed to teach everything; nor is it possible to teach everything, because what is new today is old tomorrow and discarded the next day. But the present medical curriculum is an admirable one for the teaching of principles which will make it possible for the young graduate to continue his studies and become a really good practitioner. Let the hospital people, the State Board of Examiners, and the medical school people get together and work out a plan, regardless of fixed and set state laws, entirely on an educational basis. The men engaged in this work can be trusted to do the right thing, because they are well grounded in the essentials of the job. They

know what is needed and they know what should be done to meet the needs of the situation. It is not a difficult job; on the contrary, it is comparatively easy of accomplishment if all the people concerned in it will get together and make an honest effort to work it out on the basis of needs, and not fixed standards.

I. S. Rodman, M. D., Secretary National Board of Medical Examiners—Nearly everyone will agree that, as necessary as it was to fix and maintain rigid standards of medical requirements in the years just gone by, the need for such a rigid standard has now passed. The pendulum, however, must not be allowed to swing too far backward, as it is so apt to do in any reaction. All of us thoroughly appreciate why the law back of the State Board of Medical Examiners found it necessary to safeguard such a vital matter as public health when there were over twice the number of medical schools turning out graduates as there is today. That most of these schools graduated a poorly equipped product is also well known. Much good has come, therefore, from these standards that are now, as Dr. Wilbur says, "squeezing out the life juices of intellectuality and initiative"; and good also has come from making of the study of medicine a part of the academic life of a university in recent years. We believe, however, that the safeguarding of public health is so vital a matter to the whole people that it should never be entirely free from the necessity of one's demonstrating the ability to apply the knowledge acquired in undergraduate years before being publicly declared fit for this greatest of responsibilities. We also believe that, while the majority of the medical schools existing today should be allowed a free hand in determining just how this training should be given, the product should still be judged by the measuring stick of one common standard.

This conviction has become firmly fixed with the writer after an experience of several years in examining the graduates of most of the medical schools of this country. It is inevitable, if these schools are to enjoy even greater latitude than they now do, that some of the graduates of each of them will find some subjects more interesting than others and thus slight one or more, a thorough knowledge of which is necessary to make a safe practitioner and that, of course, is the chief aim of a medical training.

Unquestionably, too much fixed instruction is now crowded into the undergraduate curriculum, and much that is now crammed into the medical student should be taught in graduate schools. Ideally there should be an "irreducible minimum" established for one to thoroughly master before being declared fit to practice medicine. Who shall set this irreducible minimum? We believe that such will come, but only through the rather tedious evolution that we are now following of free discussions of this problem by the Association of American Medical Colleges, the Council on Medical Education of the American Medical Association and others interested.

We believe that it is a matter of concern only to the medical schools themselves just how "this irreducible minimum" shall be taught; that the proper way to accomplish this end does not mean a rigid

adhering to a fixed schedule of scholastic hours, days, months, semesters and years, but that an impartial judgment should be passed on the product of such training after a thorough and searching examination into one's ability to actually demonstrate that such a training has provided this "irreducible minimum." We also believe that such qualification is best provided by one being required to show this evidence of fitness before an examining board which has the same standard for this entire country.

William Ophuls, M. D., Dean of Stanford University Medical School, San Francisco—I have read President Wilbur's address, "Maintaining Standards Without Excessive Standardization," with the greatest interest, and fully agree with him that it is foolish to let standards supplant ideals. The universities should be in a position to develop their teaching in any direction with perfect freedom and according to their best ideals, and should not be hindered in their natural development by a lot of burdensome and often unnecessary regulations. There must, however, be some control by the state relative to the entrance of university graduates to the professions, but this control should be exercised with tact and discretion and with an open mind to possible improvements in the future. What applies to all professions naturally also applies to the medical profession. *Among all others, the medical profession is the one most difficult to regulate, and judging by the protests which we hear from all sides, it is also the worst regulated one of all of them.* This is true not only with us, but practically all over the world. I need not discuss here the inherent difficulties in an attempt to control all those who wish to practice the healing art in one way or another, but the question immediately before us is, what shall be done in the case of those who have received a degree of doctor of medicine from well-recognized educational institutions like a real university. It seems a waste of time to re-examine these men after the strict examination which they have already gone through, and what is more important, the state board examinations may interfere with the proper education of the student if they insist, for instance, too much on book knowledge and give the student no opportunity to display those parts of his training which really make for future success in his profession. Such exactions may lead to slighting on the part of the students of matters of real importance in order to acquire the knowledge required to pass his state board examinations. Two remedies may be found for this situation: either the state boards may accept the examinations conducted by such institutions as equivalent to their own and admit these applicants on a "reciprocity" basis,* or they might appoint the university teachers as members of special boards of examiners who would conduct the examination for state license under the board's supervision. In the latter case the question would arise whether it would not be best to refer all candidates applying for license and to be examined to the university examining boards established in this way and distribute them among the examin-

* Such reciprocity might be established also with university medical schools outside of the state.

ing boards if there are more than one first-class university medical school in the state.

This would throw a considerable extra burden on the examiners among the university faculties, and the task should not be undertaken by them lightly on account of the real hardships connected with it, as is shown by the experience in countries where this custom prevails—for instance, in Germany. These examiners certainly should receive adequate compensation from the state for this additional work.

The boards of examiners would retain the general supervision over the medical schools in their states, but any too detailed requirements in regard to subjects taught and time spent on them should be eliminated. The boards would continue to pass on all credentials and would grant a license only when they had thoroughly satisfied themselves that the candidates actually have conformed with all general requirements in regard to the practice of medicine which the law may contain.

The whole question is one of the greatest importance to the profession, to the teaching bodies, and particularly to the public at large. We should make all efforts to increase the esteem in which the medical profession is held by the public, and this can be done only by supplying the public with physicians of the highest character and with a training that improves at the same rate as we advance in our knowledge of the science and practice of medicine. Any changes in regulations should, therefore, be considered most carefully, with this fundamental point of view in mind.

L. S. Schmitt, M. D., Acting Dean University of California Medical School—President Wilbur has pointed out that quantitative standards have served a useful purpose, but today their need is not so essential as it was twenty years ago.

Nevertheless, in a large measure, we tell the high school student intending to study medicine what he *should* do, and the collegiate and medical student what he *must* do in order to receive a degree of Doctor of Medicine.

In addition, when the candidate is enrolled in the academic departments of a university, he is required to conform to certain rules and regulations concerning prerequisites, upper and lower division courses, major and minor subjects, etc.

These restrictions have built up a long narrow passage through which all must pass. No side trips or short-cuts are permitted, regardless of the personal equation. The candidate, also, must constantly bear in mind the various requirements of the several state examining boards.

In 1914, President Lowell of Harvard concluded an address before the Tenth Annual Conference of the Council on Medical Education, with the following statement:

"Let me repeat. I am not urging the admission to medical schools of men with an inadequate preparation, but I am arguing for a measure of that preparation which shall be a real test of a man's knowledge not solely of the courses he has been through, and which will not, for a failure to decide early on his career, keep out the man of power."

(J. A. M. A., Vol. LXII, No. 11, March 14, 1914.)

Eleven years later, throughout the entire course of medical education, the necessity for such a measure is just as great.

As a result of these conditions (1) students must make their choice of a calling early in their scholastic career; (2) well-prepared students suffering from excessive formalism are debarred from Medicine as a profession; (3) medical schools lack freedom in the preparation of their curricula; (4) all students are considered to have the same intelligence quotient and identical capacity; (5) students in medical schools are measured by the number of "units" they are able to acquire rather than by their retained knowledge and power to reason.

President Wilbur has suggested certain procedures, all pointing in the right direction. These suggestions should receive wide discussion before any attempt is made to change or amend present procedures. Changes such as these should be brought about by evolutionary rather than by revolutionary methods. Perhaps many could be gradually evolved by setting up, in the various states, some machinery to control the granting of charters to educational institutions and to oversee existing institutions.

In 1910, the Academic Senate of the University of California presented a memorial to the regents to the effect that a diploma in Medicine, Dentistry, or Pharmacy from the University of California should qualify the holder to practice Medicine, Dentistry, or Pharmacy in the state of California. At that time, it was not considered feasible to recommend this procedure, but the time has now arrived when standards may be maintained without excessive formalism.

Should a degree in a learned profession, granted by a reputable university, serve as a basis for permission to practice such profession, some authority should be maintained charged with the control of law enforcement and discipline. State universities should not be required to assume this function.

Universities may eventually be utilized as agents to set a test to determine one's capability to practice a profession. Other agencies may be granted authority to revoke this privilege if it is abused.

P. T. Phillips, M. D., President California Board of Medical Examiners—The evolution of medical education has been interesting. From the scientific standpoint it has been truly wonderful in the speed of its development and in the breadth of its field. From the practical standpoint, is it satisfactory? To my mind this is the whole question.

The scientific aspects of medical instruction are bound to increase with increased facilities for investigation and research. *Will the teaching faculties of our universities, now largely influenced by full-term men with no experience in actual practice, be able, with their vision, to sift the wheat of reality from the blinding chaff of uncertain theory?* There should be employed a sufficient number of teachers experienced in all the problems the M. D. meets, to supply a practical training in the homely duties of treating the afflicted. *Helping the young practitioner to a broader, more sympathetic attitude to-*

ward the patient and his troubles is as vital to successful practice as technical foundation. An appreciation of these duties has been overlooked and neglected for the more interesting scientific investigations. *In other words, we are becoming so technical that we do not appeal to the public who are not as yet universally educated to the necessity of scientific medicine.* Much unscientific practice flourishes on the basis of sympathetic appeal, and our training schools will fall short of their obligations if they fail to recognize this element in human nature.

I am optimistic enough to believe that in another generation or two scientific medicine and no other will be demanded. This will come as a result of our present-day propaganda of health discussions in the daily papers, our health journals, and our popular health lectures by capable men added to the results accomplished by the application of intelligent hygiene and treatment. Then the M. D. degree will need no protection by legislation. In the meantime we must be patient as well as progressive, training our young practitioners to cope with the situation as it actually is and not as we hope and expect it to be. Here we may discuss medical legislation in relation to medical teaching.

All laws are for the protection of the people. Until such a time as they are sufficiently educated to refuse what is not for their good in medicine, theoretically at least, the law must protect them. The theory is right, its practice falls short because laymen make the laws, and thus unscientific as well as scientific and sound methods are allowed and upheld. The answer: Proper education inside and outside the schools. This is the only way the M. D. degree will be appreciated and protected.

Boards of medical examiners are almost entirely composed of men who are in actual practice, and I do not believe their examinations are "unimaginative," but rather of a character to better measure the practical ability of the graduate than those of the theorist and technician of the medical faculty. Medical boards do not fix the standards. The provisions of the laws are based on the advice of our teaching institutions and organizations. The boards stabilize and do not standardize the work, and with the present conditions of teaching and practice, changing like spring bonnets from year to year, I think this stabilization is necessary. If the laws contain undesirable features interfering with proper teaching, change them. In a matter of this kind we usually find our legislators sympathetic and willing to take our advice.

Percy T. Magan, M. D., Dean College of Medical Evangelists, Los Angeles—The world-old problem, how to train our youth for the most efficient service in life, has recently burst into forked flames over the question of the education of medical students. In this connection, President Wilbur's address is at once constructive and conservative—two qualifications much needed in the present hour. It is reformatory without being revolutionary. In his arguments, he, as Theodore Roosevelt would say, is traveling along a radical road in a conservative way.

There is a disposition at the present time to ruthlessly and unqualifiedly condemn all that has been

so painfully built up in the realm of medical education during the last twenty years. There is a constant harking back to the "good old days of the country doctor." Personally, I have most profound misgivings as to whether they were good days in any sense of the word. They were days when no abdominal surgery was there to snatch the sufferer from the jaws of the grave. They were days before a Semmelweiss had conquered the horrors of puerperal fever. They were days in which no Lister lived to make the operating theater safe by sterilization and antisepsis. They were days preceding Koch's isolation of the germ of tuberculosis, by which he brought from ambush the most deadly weapon in all the armamentarium of death. They were days antedating the light which radiated from the life of the immortal Pasteur. They were days before the gentle soldier physician, Ronald Ross, had discovered that "little thing" which "a myriad men" has saved. Surely the processes of medical study, education and research of modern times have brought forth from the womb of mystery thousands of blessings to man and womankind. Nowadays it seems to be even popular to bless the past and curse the present. However, the highway of history would seem to reveal that such has been a favorite pastime in all ages, for Professor Gilbert Murray of Oxford tells us that one of the oldest documents known to man—a cuneiform fragment from the lowest, most ancient stratum of the ruins of Babylon—begins with these words, "Alas! alas! times are not what they were!"

No, the "good old days" were, methinks, not so good after all. The constant glorification of them by people who know a lot that isn't so brings to mind a quaint little anecdote of an Englishman who mourned to a North Briton, "I greatly fear the London Times is not nearly so well edited as it used to be." To which the canny Scot replied: "I hae mae doubts if it ever was." However, these folk who are so busy trying to reform everything that everybody else is doing seem to be worse than their ancestors in that, as General Booth of the Salvation Army once put it, "the priest and the Levite of the present day differ from their forebears, in that they not only pass by on the other side, but return and vigorously punch the head of any good Samaritan who attempts anything really worth while."

I have listened to and read much learned prattle of late that young men and women should be taken direct from high school and placed at once in the medical college without any pre-medical college training. Besides, it is further argued that the course in medicine need not exceed three years in length. In support of these contentions, it is urged that many a good doctor in an earlier day had no more than grammar schooling and a two years' medical course.

The fallacies of these proposals can be easily understood when the tremendous responsibilities of the present-day doctor are compared with those of his predecessors. *Compare, for instance, the responsibilities of the physician of some years ago and to-day in the case of acute appendicitis.* This disease was undiagnosed then, and there was no surgery for its relief. The patient got a pain; the doctor came

and talked about "inflammation of the bowels," and prescribed a cathartic and possibly some warm applications. If the patient got well, the doctor received praise he did not deserve. If he died, the Almighty got blamed for what he did not deserve. Take affections of the gall-bladder, which now call for cholecystectomy or cholecystotomy, as the case may be. In those days the doctor treated them much the same as he treated appendicitis, and with similar results. Or, think of carcinoma of the uterus. Well, the poor woman "had a lump," for which nothing could be done, and the ways of Providence in taking such a good mother away from her family were surely a mystery hard to be understood. Or, in the realm of internal medicine, when a person was stricken with diabetes, special diet might be resorted to, but that was all. In a case of cretinism, all the doctor had to do was to tell how sorry he was and prescribe plenty of wholesome food and fresh air. And so I might proceed *ad infinitum*. Nowadays, however, it is much more difficult for the doctor to lay his ignorance as a loving offering at the feet of the Eternal's Throne than it was in "the good old days." He must *know* whether the case is appendicitis, or intussusception, or gall-stones, or gastric ulcer, or what not. He must *know* how to differentiate correctly between all of these. He must *know* how to operate in each particular case, or he must know when the difficulty is beyond his power to do and have sense sufficient to take the patient to somebody else. He must know how to administer insulin and carry a most elaborate and scientific dietetic program along with his insulin therapy. He must know what thyroid or iodine will do for cretinism, and he must know it in a most precise, mathematical and scientific way. And if he does not know all these things theoretically and practically, he is very liable to find himself faced with most expensive damage suits, and un pitying publicity. Verily, there is no comparison between the doctor's responsibilities today and the responsibilities of those who trod his professional path in days of yore. And yet we are expected to teach him all of these things in the same length of time in which preceptors of by-gone days imparted their little stock of medical lore to those who sat at their feet.

I have all respect for the great work which the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges have done. To disparage the labors and achievements of these earnest men is just a case of punching the head of the Good Samaritan. We must remember that medical education is a legal even more than a medical question, and that the difficulties of honest reform are Herculean. It is true that there is danger of overstandardization. Our courses of study are not sufficiently flexible. But these things require not only wise experiment for their solution; they also require in the aggregate the expenditure of vast sums of money to secure their successful accomplishment. And on top of this a world of work educating legislators and laymen to amend or abrogate old laws is necessary. And, in the homely language of the Sunday-school boy when the teacher told him, "Johnnie, God can do everything," Johnnie blasphemously replied, "No, Miss Mary, He can't make a three-year-old

calf in a minute." Equally, all these things cannot be accomplished by the wave of a magic wand, as our idealistic friends seem to suppose.

Great reforms are being made all the time. By clinics in the first and second years in the medical course, the great gulf between the ancillary and the clinical years is being bridged. Our little school is endeavoring to work out the experiment of placing freshman and sophomore medical students in hospitals and other medical institutions during every other month of their medical course. They work as orderlies, aides, assistants, and technicians of one sort or another. In this way they are brought into a place where they absorb the patient's angle of vision, of the care and treatment he is receiving. They come into humble and intimate touch with him and with the women who are nursing him, and thus a better understanding of the viewpoint of the patient, of his relatives, and of the hospital is secured, and the student becomes possessed of a much more sympathetic and, may I say, spiritual knowledge of his patient's needs. We are hoping that this contact will have a tendency to neutralize the alleged haughtiness, uppishness, and lack of kindly feeling toward their patients with which doctors are being so freely charged at the present time. We hope it may help in impregnating the students with the quaint and deeply valuable philosophy of King Solomon: "Be not righteous overmuch; neither make thyself overwise; why shouldst thou destroy thyself?"

I do think that times are changed, and that the work of the Council on Medical Education is so firmly enwrought in the public conscience that we might now safely make some modifications in the powers of State Boards of Licensure. *It is possible that a plan might be worked out to examine the medical school rather than the medical student, and to trust the examination of the medical student to the medical school instead of the unmedical state.* In any event, the object of the state board examinations should be directed toward a plan designed to ascertain the capacity of a would-be practitioner to think and to do rather than to an examination of his powers of memory, which in many instances is about all a state board examination amounts to. In fact, some state board examiners remind me of what Lord Macaulay once said of the Dons of Oxford, that the greater their erudition, the denser their ignorance of what was really required of them. State board examiners need to imbibe the philosophy of the great Billroth: "The sum of the contents of memory at any moment is no measure of the capacity of a man. We forget much, but if we have practiced in a certain kind of thinking, it, like the ability to swim, will never be lost as long as we retain the full use of our mental powers."

"By the Term, 'Allied Sciences,' as applied to medicine, is meant those subdivisions of general science that are held by teaching institutions of standing and reputation conferring the degree of Doctor of Medicine to have a place in the professional education and training of a physician."

Since the number of medical schools has been greatly reduced, and the requirements for medical education have become more uniform, it is easier to determine whether medical schools are fulfilling all necessary requirements.—Federation Bulletin.

CALIFORNIA'S LEAGUE FOR THE CONSERVATION OF PUBLIC HEALTH

By WALLACE I. TERRY, M. D., San Francisco

INTRODUCTORY NOTE

Doctor Terry's remarkably able review of some of the important work of the League for the Conservation of Public Health should inspire every true physician to renewed efforts in the public welfare. It outlines an amazing record of a unique and remarkable organization devoted solely to the interests of better health for all Californians.

The weakest link in the forward march of applied medicine is admittedly the lack of sufficiently cohesive intelligent action. Retail medicine as practiced by individual doctors for individual patients is advancing faster than is mass medicine for the masses. This latter field of applied public health is so intricately honeycombed with associations and organizations, political, altruistic, mercenary, and what not, that they get into each other's way and slow up progress. They fail to combine on most matters of moment and consequently they accomplish little in those places where accomplishments are wisely effective.

The League for the Conservation of Public Health has done, and is doing, more intelligently effective work for the cause of better health than are all other groups combined. It has done and is doing more to cement worthwhile individual doctors together so as to bring coherent mass action to bear upon the vital problems of health than is any other influence. Its membership includes only the kind of doctors we all wish we were and strive to be. The other kind—and they are few—are its enemies, which is the greatest compliment the League could have. There are classes and classes of doctors as there are classes and classes of other people. The League membership roll comes nearer being a directory of the kind of doctors another doctor wants when he is ill, or who are sure to be as interested in public health as they are in the personal health of their individual patients, than any other group anywhere.

An occasional doctor—usually an uninformed or disgruntled one—wants to know why the California Medical Association cannot do all the things that the League does. Any thinking person would find enough of an answer by reading the constitution of the California Medical Association. The House of Delegates several years ago were so favorably impressed with the work of the League that they unanimously invited the League to act as the California Medical Association's section on Medical Economics, Hospitals, Public Health, Medical Legislation, and similar matters. This fine co-operative spirit has continued to produce the most effective kind of harmonious team work.

Better Health magazine and the Better Health Service are the most effective answer that has been provided anywhere to the justifiable demand for authoritative information about health for the man on the street. The secret of that success, as Doctor Terry says, is impersonal service given out under the name of an organization rather than by any one man. That it is effective, is most amply demonstrated by the more than 100,000 letters of inquiry, comment, and commendation its editors have received and answered in the last four years.

Not only every physician, but every other person genuinely interested in the health welfare of his fellow-men should read Doctor Terry's able analysis of the doings of the League for the Conservation of Public Health.—
EDITOR.

SOME ten years ago the medical profession of California was faced with a momentous question of medical economics. An imported plan for the medical and hospital care of a large percentage of the population was plausibly presented and actively promoted by prominent doctors and laymen with the support of influential official groups. Social Health Insurance was the attractive name of a "panel system," which, it was claimed, would im-

prove medical service and solve the financial problems of physicians and patients.

The doctors divided and disagreed upon the question, and debates before the various societies produced much heat, but little light. Leaders of the American Medical Association, including the president, were outspoken in favor of the measure. The California State Medical Society remained neutral and declined to oppose social health insurance. The advocates of the new proposition were naturally confident because they had the distinct advantage of organization, "statistical" reports, publicity and official endorsement. The question became a burning issue and, after several years of propaganda, the legislature was induced to place social health insurance upon the ballot as a constitutional amendment to be decided at the general election November 8, 1918, by the vote of the people of California.

Some of the doctors who believed that the movement was a menace, and that the compulsory, paternalistic measure proposed would not only undermine the efficient voluntary hospital and medical service of California, but also take away the individual independence of the doctors, resolved that something had to be done to defeat the measure. They recognized, however, that resolutions were futile, and that to make their opposition effective they must have an organization to conduct an aggressive campaign. They realized that to depend upon other organizations that were dividing and confusing the issue would get them nowhere. And so it happened that leading members of the medical profession of Southern, Central, and Northern California organized the League for the Conservation of Public Health.

DEFEAT OF SOCIAL HEALTH INSURANCE

How efficient the League was in conducting that decisive statewide campaign, and how effective its publicity and literature proved, can all be summed up in the single statement: The League defeated social health insurance, despite all its propaganda, official endorsements and influential backing, by the conclusive majority of 224,466.

The sound judgment of the doctors of California in forming an independent organization was vindicated. The practical need and value of such an organization was quickly recognized, and so the League for the Conservation of Public Health has continued to meet its growing responsibilities with increasing effectiveness.

Since its first statewide campaign eight years ago, the League has blazed many a pathway in the field of publicity, legislation, medical economics, education, and hospital betterment. Its activities have steadily increased in response to urgent demands for its co-operation and counsel. The purposes of the League, as summarized on the organization's letterhead, are: To spread wider and more accurate knowledge of what scientific medicine is doing and can do for the promotion of health, the prevention, control and limitation of the various diseases; to counteract pernicious propaganda and warn the people of the dangers of quackery by presenting reliable information through Better Health, Better Health Service, and other proper channels of publicity; to encourage the enactment and enforcement

of better health laws; to promote and maintain more and better hospitals wherein educated physicians may render better service to every community of California. This is the constructive program upon which the League rests its right to claim the approval of the public and the profession. It is a worthy program, and it demands an efficient organization to carry it on worthily. Each of the several types of service which the League renders requires specialized knowledge, experience, and executive ability. Doctors, more than any other group, appreciate the need for training, information, special data, and thorough examination before making a diagnosis. To diagnose a publicity problem, a legislative problem, a problem that may involve the changing of public opinion, or of official attitude, or of community sentiment or prejudice, or a mass of more or less unsound views, or finding and informing the factors that make or break any movement—these things often require much investigation and a more searching history than is often needed for the diagnosis of hidden troubles of an individual patient.

The progress of medical science, of medical colleges, hospitals, laboratories, health departments, and all agencies of scientific health work are becoming more and more dependent upon the education of the public, the action of legislatures and the co-operation of communities. It is generally acknowledged that the medical profession has ample scientific knowledge and experience now at hand, if it were universally applied, or even accepted by the vast majority of people, to prolong the average human life many years and make all the years more efficient and happy. The development of the League is bound up with the welfare of California, for as the League's slogan aptly expresses it, "The Health of the People is the Wealth of the State."

PUBLICITY MOULDS PUBLIC OPINION

Public opinion is the most potent force in putting "over" or putting "under" any movement. Public opinion cannot be reduced to charts, curves and cycles, but it can be fairly well gauged by a student of publicity who can diagnose its trends and who has newspaper experience in analyzing its growth, climax, and decline, and can interpret the behavior of crowds. The most powerful moulder of public opinion is publicity, and it can be made the strongest ally of scientific medicine. There is plenty of evidence that the misrepresentation and misinformation that is constantly being spread by anti-scientific groups in scores of magazines and hundreds of newspapers is undermining public confidence in scientific medicine. Busy doctors have been so preoccupied and so self-satisfied that they have overlooked the trouble-making possibilities of the cults and their growing capacity to handicap and hinder the practice and progress of medicine.

A national magazine stated last year, after a survey of the second largest city of the United States, that only 33 per cent of the people, when sick, relied upon the services of educated physicians. The other 67 per cent divided their patronage among the various cults, charlatans, religious healers, physical culturists, semi-educated practitioners, patent medicine vendors, and what not. The commercial

success of the anti-scientific forces was attributed to publicity and political activity.

The League has proven in California that most people prefer authoritative information on health subjects when they understand where to get it and what "authoritative" is. The public cannot co-operate intelligently with the medical profession without the facts, and the facts must be presented in language they can understand. We have no reason to fear the verdict of fair-minded people when they know the facts.

The League, through its Better Health Service, which is published every day of the year, is furnishing the facts to hundreds of thousands of readers of what scientific medicine is prepared to do for the promotion of health and the prevention, control, cure, and relief of sickness. "Give the people the light," said Dante, "and they will find their own way."

To answer pernicious propaganda through medical journals is ineffective, for the laity do not read them. It may be answered effectively in two ways: through the newspaper, which is the daily textbook of the people, or through a popular magazine sold at news stands. The League does both and has won the highest commendation of leading publishers, editors, officials, doctors, educators, legislators, and thousands of appreciative letters from readers generally. The League is giving the medical profession publicity that is creating good-will that cannot be bought at any price.

It is obvious that the quality of service which the League is giving newspapers cannot be handled as a side issue or in haphazard fashion. We know that spasmodic articles can accomplish very little, and that we must not only inform the public, but keep on informing them.

BETTER HEALTH SERVICE

Better Health Service is more than the stereotyped newspaper articles on health subjects that are mere expressions of opinion of individual writers. The Better Health Service, organized by the League, struck the keynote for the new order of impersonal publicity. As all the other League activities, its popular newspaper service is entirely impersonal, which has won for it the widest approval and support of the medical profession. The impersonal policy overcomes the very proper objection leveled at many newspaper health columns that exploit and advertise individual doctors.

In looking over the four past years of the League's daily and Sunday Better Health Service, we find hundreds of valuable messages on important aspects of medical work that serve to clear up misunderstandings, correct misinformation, and place convincing facts before the people. The articles and answers are not theoretical or technical, but contain the kind of practical and reliable information that the reading public needs and wants. Over three hundred leading surgeons and physicians, dentists, health authorities and specialists in the various branches and fields of medical, hospital, and public health work, contribute to the League's Better Health Service.

Thousands of letters are received by the Better

Health Service, which give an index to what people are saying and thinking about doctors, hospitals, clinics, welfare movements, etc. The questions asked and the answers given to the questions react further and touch deeper than anyone unfamiliar with the active interest of the public in health subjects may think.

It is a fine thing for the public as well as for the profession to have such a reliable health service, and the people appreciate it. But it must not be overlooked that the League's daily and Sunday Better Health Service demands a vast amount of tireless and unrespired hard work, both daily and Sunday. Its responsibilities are always great and sometimes grave. The opportunities for costly mistakes are ever present. That none have occurred in four years of steady work, is a sufficient endorsement of the high quality of the service and the care and capacity of its management.

The publicity service of the League embraces more than furnishing material to the press and magazines. The League is on terms of cordial co-operation with the press and often is called upon for information, and many times keeps sincere editors from being imposed upon by new "cures" and old frauds.

PIONEER POPULAR HEALTH MAGAZINE

Some essential health, hospital, and medical subjects cannot be adequately discussed in mass-circulation newspapers. It is obvious that many newspapers do not wish to lose certain advertisers and subscribers. The League established the pioneer popular health magazine, *BETTER HEALTH*, to supplement the Better Health Service. Its title is considered so valuable, as it so appropriately expresses the magazine's mission, that not a few have tried to borrow, buy, or steal it. It is a different kind of magazine from any published, and it does not duplicate or imitate any other periodical. *BETTER HEALTH* has no trammeling connections whatsoever. It knows and reflects California, although there is nothing provincial about it.

At the 1925 session of the legislature, and during several previous sessions, the League's position on important bills was clearly set forth in *BETTER HEALTH*. Leading legislators expressed approval and appreciation of this valuable service. In every session of the legislature bills are introduced that are highly prejudicial to medical practice, medical research, to the teaching of medicine, to hospital administration, nursing education and public health protection. I cannot attempt to give in this paper a detailed review or even a complete outline of the work which the League has done during the last four sessions of the legislature. It would require a series of papers to do the subject justice. The records show that much dangerous legislation which would have jeopardized important health agencies would have passed if the League were not on the job, and a number of constructive measures would have been defeated without League support. Time and again the League has been called upon by hospitals, medical colleges, groups of doctors, nurses, dentists, veterinarians, public health officials, social workers, women's clubs, and other groups interested

in some angle of health work. When the League is convinced it has always responded effectively.

SOME LEGISLATIVE ACTIVITIES

I can mention only a few of the long list of legislative activities of the League: In two statewide campaigns and in three legislative sessions, the League opposed anti-vivisection. People throughout the country were profoundly concerned in the outcome, for a victory by the anti-vivisectionists would nullify the advances made by scientific medicine in recent decades. In each instance the League won by an impressive vote. A measure which Illinois permitted to pass was introduced as an economy measure by the administration here to combine and place the Board of Medical Examiners, Board of Dental Examiners, Board of Optometrists, State Board of Embalmers, Board of Examiners in Veterinary Medicine, Board of Pharmacy, boards of architecture, librarians, accountancy, all in one Department of Professional Standards. The law provided that a layman was to be appointed director of the new department by the Governor, with full power to issue licenses to practice for all professions and to suspend and revoke licenses. The League's courage to challenge, and its judgment in fighting and defeating this dangerous measure, is now acknowledged by all. In the last session of the legislature a measure was offered by a certain cult that would have made treatment by prayer or any spiritual means a sufficient and full compliance with all the provisions of the Workmen's Compensation Act. If adopted, it would have demoralized industrial, medical and hospital service and added to the complicated problems of industry, additional health hazards and controversial religious problems. Under the provisions of the Act, spiritual healers of any and all sects could treat cuts, breaks, fractures, lead poisoning, hernia, valvular heart defects, tuberculosis, defective vision, burns, syphilis, communicable and infectious diseases, and all the shocks and ailments that industry is heir to. One would think that manufacturers, insurance companies, labor organizations, railroads, and those who know the constant need of medical and surgical service in industry would hasten to Sacramento to fight a measure that affected them so vitally. The reverse was the case. The fighting was left to the League. The proposed law was defeated by a very narrow margin. Bills to unionize nurses, x-ray bills, bills that would license persons to practice without adequate education, milk bills that would impose costly and unnecessary requirements on hospitals, hospital bills that would jeopardize the interests of worthy hospitals and their patients, many kinds of disguised paternalistic measures, anti-health bills of all varieties were successfully opposed by the League.

Constructive legislation to provide adequate facilities for the study and treatment of mental diseases, to provide better hospital service for the needy sick, to surround the title of doctor with definite legal safeguards and protect the public from misrepresentation, imposition and fraud of advertising doctors, legislation to meet the demands of the research, laboratory, anatomical and other departments of the medical colleges of California, anti-diploma mill bills were promoted by the League. On the agitated

question of narcotic drug addiction the League has done a great deal of investigating, held conferences and co-operated with groups intelligently and seriously interested in handling the problem under proper institutional conditions medically supervised. The League sponsored and passed the first anesthetic bill passed anywhere. A new optometry bill was passed which restored rights to oculists and other physicians and removed arbitrary regulations from skilled manufacturing opticians. The old law created a virtual commercial monopoly in favor of optometrists, and oculists keenly felt its unfair restrictions on their practice. How profitably certain groups of optometrists used the old law was made clear. The optometry law just passed curbs the monopoly of the optometrists, and is of benefit not only to physicians, but to their patients who must wear and pay for glasses.

THE PENALTY OF LEADERSHIP

The League is not boastful, as it realizes that all victories are temporary, and that eternal vigilance is the price of medical freedom, the same as it is the price of commercial, religious, and political freedom. At intervals, some disgusted doctor, after reviewing the many quacks, fakes, anti-medical movements and the many problems that remain unsolved asks, "What's the use? Cultists continue to multiply, the politicians continue to side-step, the public is indifferent, and why should we worry about what happens to our successors?"

In all other fields the people bear the burdens of their day. The penalty of leadership is to meet constant opposition. In all contests competitors try to knock the leaders off their pedestals. This can be escaped only by those who avoid responsibilities.

A few seem to think that quackery is benefited and not injured by adverse legislation and publicity. They assert that if physicians were rendering the high type of service that we should render that there would be no room for quackery, and it would disappear from lack of patronage. This viewpoint is unsound and contrary to direct and collateral evidence. It is not alone in the field of medicine, in the selecting of doctors, that people make serious mistakes. There is nothing wrong with the legal coin of our country minted by the Government; nevertheless, counterfeiters unopposed and unexposed would flourish and pass spurious coinage and victimize many in every community. No thoughtful person interprets the fact that billions of dollars are wasted annually in wildcat schemes and on worthless stocks as a reflection on the standard stocks that are as good as gold. The Government knows and financiers appreciate that they must keep the public informed and be vigilant themselves when laws are being made which they must observe. Without information, without the facts, the public has no way of distinguishing the true from the false, the counterfeit doctor from a genuine physician. When the profession is indifferent to what the public thinks, it follows naturally that the public becomes indifferent to what the profession thinks.

The League's influence at the legislature and on political thought has increased steadily because it has acquired the reputation of fairness, accuracy, and fearlessness. One of the chief reasons why the

League has been so surprisingly right on most questions is that it consults so many sources and gets information and opinions from all angles. The League never endorses, advocates or opposes a bill or a policy until it has examined the various sources of information. The League takes time to gather evidence and does not try to force its opinion or conclusions on anyone. It submits them with candor on their merit. One thing is sure, the League is not afraid to act, and it does not act one thing and believe another.

A discussion of men and measures at the League office is always illuminating. It brings out angles, background, motives, inducements, financial interests, fraternal, club and social ties in significant relationships. The League is a clearing house of legislative information and can tell you why certain legislators voted for and against measures and why certain doctors were neutral and the reason for the opposition of others. Why one organization reversed itself three times on one measure and why some chambers of commerce were silent and others endorsed the cult viewpoint on legislation. Lincoln once said: "Now, there's Mr. ——. He thinks he is fooling me. I let him think so, but I don't let him fool me." It must be borne in mind that much of the information received by the League is confidential, and will be used only in the interests of its service, but will not be disclosed.

HOSPITAL BETTERMENT SERVICE

The League has confidential information about hospitals, for instance, which, if blazoned forth, would be a seven-day sensation and do irreparable damage. But the League Hospital Betterment Service is constructive and works for the benefit of all. In addition to the important legislative and publicity work which the League does for hospitals, it answers numerous calls for assistance from all parts of the state and on all sorts of problems, from expansion and new construction to reorganization of staff, school of nursing, record systems and questions relating to every other department. "Hospital betterment" is a term coined by the League, and in California means service—active and operative every hour of the day and night to every patient in the hospital.

When the League began its hospital betterment work in 1918 no one had collected the facts about ownership, costs, number of beds or where new hospitals were most needed, and no one had sufficient information to even guess at the character of service which the hospitals of California were rendering or prepared to render to the people of the state. There was no generally accepted definition of what a hospital should be, no comprehensive record policy, accounting system, and no firm policy with regard to cults. In the October issue of *BETTER HEALTH* the foresight of the League on this dangerous question is shown in the article on page 401, entitled "Invasion of Hospitals by the Cults."

The first convention of the hospitals of California was called by and held under the auspices of the League for the Conservation of Public Health, and these annual hospital conventions are proving of the utmost interest and benefit to the directors, admin-

istrators, staff, nurses, and technicians in solving common hospital problems.

A Certificate of Honor, signed by Dr. Ray Lyman Wilbur as president of the American Medical Association, was awarded "The League for the Conservation of Public Health for the exhibit relating to hospital betterment, Better Health Service, the state campaigns for high standards of medical practice and for the improvement of laws relating to preventive medicine and the prevention of legislation that would lower the standards of health and retard the progress of medicine."

EXTENSION OF "CALIFORNIA PLAN"
